

## GROMOV-WITTEN INVARIANTS OF THE HILBERT SCHEME OF 3-POINTS ON $\mathbb{P}^2$ \*

DAN EDIDIN<sup>†</sup>, WEI-PING LI<sup>‡</sup>, AND ZHENBO QIN<sup>§</sup>

**Abstract.** Using obstruction bundles, composition law and localization formula, we compute certain 3-point genus-0 Gromov-Witten invariants of the Hilbert scheme of 3-points on the complex projective plane. Our results partially verify Ruan’s conjecture about quantum corrections for this Hilbert scheme.

**1. Introduction.** Motivated by the pioneering work of Nakajima and Gromowski [Nak, Gro], there have been intensive studies of the cohomology ring structure of the Hilbert schemes of points on a smooth algebraic surface (e.g. [Leh, L-S, LQW1, LQW2, LQW3, Q-W, Go2]). While our understanding of this ordinary cohomology ring structure has deepened rapidly, the quantum cohomology ring structure of these Hilbert schemes remains to be a mystery. A limited progress to the quantum cohomology ring structure has been made in [L-Q] where certain 1-point genus-0 Gromov-Witten invariants of these Hilbert schemes have been determined. These 1-point invariants come from the contributions of curves contracted by the Hilbert-Chow map from the Hilbert schemes to the symmetric products of the surface.

In this paper, we study 3-point genus-0 Gromov-Witten invariants of the Hilbert scheme  $(\mathbb{P}^2)^{[3]}$  of 3-points on the complex projective plane  $\mathbb{P}^2$ . Again, we are primarily interested in those invariants which come from the contributions of curves contracted by the Hilbert-Chow map (2.8). These curves are homologous to  $d\beta_3$  for some positive integer  $d$ , where  $\beta_3 \subset (\mathbb{P}^2)^{[3]}$  is the rational curve defined by

$$\beta_3 = \{\xi + x_2 \mid \ell(\xi) = 2, \text{Supp}(\xi) = x_1\}$$

with  $x_1$  and  $x_2$  being two fixed distinct points of the projective plane  $X = \mathbb{P}^2$ .

To state our main results, we introduce some notations. Let  $H^*(X^{[3]})$  and  $H_*(X^{[3]})$  be the cohomology and homology of  $X^{[3]}$  with  $\mathbb{C}$ -coefficients. For  $i = 2, 4, 6, 8, 10$ , a linear basis  $\mathfrak{B}_i$  of  $H_i(X^{[3]})$  in terms of the Heisenberg operators introduced in [Nak, Gro] can be determined (see Lemma 2.3 and Definition 2.4 for details). For  $\alpha_1, \dots, \alpha_k \in H^*(X^{[3]})$ , we use  $\langle \alpha_1, \dots, \alpha_k \rangle_{0,d}$  to stand for the  $k$ -point genus-0 Gromov-Witten invariant  $\langle \alpha_1, \dots, \alpha_k \rangle_{0,d\beta_3}$ . Now the 3-point genus-0 Gromov-Witten invariants  $\langle \alpha_1, \alpha_2, \alpha_3 \rangle_{0,d}$  of  $X^{[3]}$  are reduced either to the 2-point invariants  $\langle \text{PD}(A_1), \text{PD}(A_2) \rangle_{0,d}$  with  $A_1 \in \mathfrak{B}_6$  and  $A_2 \in \mathfrak{B}_8$ , or to the 3-point invariants  $\langle \text{PD}(A_1), \text{PD}(A_2), \text{PD}(A_3) \rangle_{0,d}$  with  $A_1, A_2, A_3 \in \mathfrak{B}_8$ . Here PD denotes the Poincaré duality. Our main results are the following.

**THEOREM 1.1.** *Let  $X = \mathbb{P}^2$ , and  $\mathfrak{B}_6$  and  $\mathfrak{B}_8$  be defined in Definition 2.4. Let  $d \geq 1$ ,  $A_1 \in \mathfrak{B}_6$  and  $A_2 \in \mathfrak{B}_8$ . Let  $x, \ell$  be a point and a line in  $X$  respectively. Then,  $\langle \text{PD}(A_1), \text{PD}(A_2) \rangle_{0,d}$  is zero unless the pair  $(A_1, A_2)$  is one of the following:*

- (i)  $(\mathfrak{a}_{-2}(X)\mathfrak{a}_{-1}(x)|0\rangle, \mathfrak{a}_{-1}(X)\mathfrak{a}_{-2}(\ell)|0\rangle)$
- (ii)  $(\mathfrak{a}_{-2}(\ell)\mathfrak{a}_{-1}(\ell)|0\rangle, \mathfrak{a}_{-2}(X)\mathfrak{a}_{-1}(\ell)|0\rangle)$
- (iii)  $(\mathfrak{a}_{-3}(\ell)|0\rangle, \mathfrak{a}_{-3}(X)|0\rangle)$ .

Moreover,  $\langle \text{PD}(A_1), \text{PD}(A_2) \rangle_{0,d} = 12/d$  in cases (i) and (ii).

**THEOREM 1.2.** *Let  $X = \mathbb{P}^2$ , and  $\mathfrak{B}_8$  be defined in Definition 2.4. Let  $\ell \subset X$  be a line. Let  $d \geq 1$ ,  $f(d) = d \langle \text{PD}(\mathfrak{a}_{-3}(\ell)|0\rangle, \text{PD}(\mathfrak{a}_{-3}(X)|0\rangle) \rangle_{0,d}$ , and  $A_1, A_2, A_3 \in \mathfrak{B}_8$ . Then, the 3-point genus-0 Gromov-Witten invariant  $\langle \text{PD}(A_1), \text{PD}(A_2), \text{PD}(A_3) \rangle_{0,d}$  is zero unless the unordered triple  $(A_1, A_2, A_3)$  is one of the following:*

- (i)  $(\mathfrak{a}_{-2}(X)\mathfrak{a}_{-1}(\ell)|0\rangle, \mathfrak{a}_{-2}(X)\mathfrak{a}_{-1}(\ell)|0\rangle, \mathfrak{a}_{-1}(X)\mathfrak{a}_{-2}(\ell)|0\rangle)$
- (ii)  $(\mathfrak{a}_{-3}(X)|0\rangle, \mathfrak{a}_{-3}(X)|0\rangle, \mathfrak{a}_{-2}(X)\mathfrak{a}_{-1}(\ell)|0\rangle)$
- (iii)  $(\mathfrak{a}_{-3}(X)|0\rangle, \mathfrak{a}_{-3}(X)|0\rangle, \mathfrak{a}_{-1}(X)\mathfrak{a}_{-2}(\ell)|0\rangle)$
- (iv)  $(\mathfrak{a}_{-3}(X)|0\rangle, \mathfrak{a}_{-3}(X)|0\rangle, \mathfrak{a}_{-3}(X)|0\rangle)$ .

Moreover,  $\langle \text{PD}(A_1), \text{PD}(A_2), \text{PD}(A_3) \rangle_{0,d} = -24$  for case (i); for cases (ii) and (iii),  $\langle \text{PD}(A_1), \text{PD}(A_2), \text{PD}(A_3) \rangle_{0,d} = -2f(d)$ ; for case (iv),

$$\begin{aligned} & \langle \text{PD}(A_1), \text{PD}(A_2), \text{PD}(A_3) \rangle_{0,d} \\ &= -162 - 15f(d) + 6 \sum_{0 < d_1 < d} f(d_1) + \frac{1}{3} \sum_{0 < d_1 < d} f(d_1)f(d - d_1). \end{aligned}$$

These two theorems are proved by using obstruction bundles and composition laws in Sect. 3, which generalizes the earlier methods in [L-Q]. In view of our theorems, to compute all the 3-point invariants  $\langle \alpha_1, \alpha_2, \alpha_3 \rangle_{0,d}$  of  $X^{[3]}$ , it remains to determine the 2-point invariant  $\langle \text{PD}(\mathfrak{a}_{-3}(\ell)|0\rangle, \text{PD}(\mathfrak{a}_{-3}(X)|0\rangle) \rangle_{0,d}$ . In Sect.4, using the standard  $(\mathbb{C}^*)^2$ -action on  $X = \mathbb{P}^2$  and the virtual localization formula from [G-P], we reduce the computation of  $\langle \text{PD}(\mathfrak{a}_{-3}(\ell)|0\rangle, \text{PD}(\mathfrak{a}_{-3}(X)|0\rangle) \rangle_{0,d}$  to a summation over stable graphs. Even though we could not simplify this summation for a general  $d$ , we are able to calculate the summation for  $d \leq 4$  by employing Mathematica. This enables us to prove the following.

**PROPOSITION 1.3.** *Let  $X = \mathbb{P}^2$ , and  $\ell \subset X$  be a line. Then, the 2-point genus-0 Gromov-Witten invariant  $\langle \text{PD}(\mathfrak{a}_{-3}(\ell)|0\rangle, \text{PD}(\mathfrak{a}_{-3}(X)|0\rangle) \rangle_{0,d}$  is equal to  $-27, 27/2, 18$  and  $27/4$  when  $d$  is equal to 1, 2, 3 and 4 respectively.*

One of our motivations for this present work is to verify Ruan’s conjecture in [Ru2] about the quantum corrections for crepant resolutions of orbifolds. The symmetric products of a smooth projective surface are global orbifolds. The Hilbert-Chow map (2.8) presents the Hilbert schemes of points on a smooth projective surface as crepant resolutions of the symmetric products of the surface. For the Hilbert scheme  $(\mathbb{P}^2)^{[3]}$ , our results enable us to verify Ruan’s conjecture for those quantum corrections not involving  $\langle \text{PD}(\mathfrak{a}_{-3}(\ell)|0\rangle, \text{PD}(\mathfrak{a}_{-3}(X)|0\rangle) \rangle_{0,d}$ . Since the verification involves only straight-forward computations, we omit the details.

Finally, we remark that our methods can be extended in several directions. First of all, they can be used to compute many 3-point Gromov-Witten invariants of the Hilbert scheme  $(\mathbb{P}^2)^{[n]}$  for a general  $n$ . Secondly, our methods of proving Theorem 1.1 and Theorem 1.2 can be easily modified to work for an arbitrary simply connected projective surface  $X$ . In addition, the ideas of proving Proposition 1.3 can be applied to other toric surfaces. We leave the details to the interested readers.

**Acknowledgments:** The authors thank Y. Ruan for stimulating discussions. The third author also thanks Hong Kong UST for its warm hospitality and support.

2. Preliminaries.

**2.1. Stable maps and Gromov-Witten invariants.** Let  $Y$  be a smooth projective variety. A  $k$ -pointed *stable map* to  $Y$  consists of a complete nodal curve  $C$  with  $k$  distinct ordered smooth points  $p_1, \dots, p_k$  and a morphism  $\mu : C \rightarrow Y$  such that the data  $(\mu, C, p_1, \dots, p_k)$  has only finitely many automorphisms. In this case, the stable map is denoted by  $[\mu : (C; p_1, \dots, p_k) \rightarrow Y]$ . For a fixed homology class  $\beta \in H_2(Y; \mathbb{Z})$ , let  $\overline{\mathfrak{M}}_{g,k}(Y, \beta)$  be the stack parameterizing all the stable maps  $[\mu : (C; p_1, \dots, p_k) \rightarrow Y]$  such that  $\mu_*[C] = \beta$  and the arithmetic genus of  $C$  is  $g$ . It is known [F-P, LT1, LT2, B-F] that  $\overline{\mathfrak{M}}_{g,k}(Y, \beta)$  is a complete Deligne-Mumford stack with a projective moduli space. Moreover, it has a virtual fundamental class  $[\overline{\mathfrak{M}}_{g,k}(Y, \beta)]^{\text{vir}} \in A_{\mathfrak{d}}(\overline{\mathfrak{M}}_{g,k}(Y, \beta))$  where

$$\mathfrak{d} = -(K_Y \cdot \beta) + (\dim(Y) - 3)(1 - g) + k \tag{2.1}$$

is the expected complex dimension of  $\overline{\mathfrak{M}}_{g,k}(Y, \beta)$ , and  $A_{\mathfrak{d}}(\overline{\mathfrak{M}}_{g,k}(Y, \beta))$  is the Chow group of  $\mathfrak{d}$ -dimensional cycles in the stack  $\overline{\mathfrak{M}}_{g,k}(Y, \beta)$ . The evaluation map

$$ev_k : \overline{\mathfrak{M}}_{g,k}(Y, \beta) \rightarrow Y^k \tag{2.2}$$

is defined by  $ev_k([\mu : (C; p_1, \dots, p_k) \rightarrow Y]) = (\mu(p_1), \dots, \mu(p_k))$ .

The Gromov-Witten invariants are defined by using the virtual fundamental class  $[\overline{\mathfrak{M}}_{g,k}(Y, \beta)]^{\text{vir}}$ . Recall that an element  $\alpha \in H^*(Y) \stackrel{\text{def}}{=} \bigoplus_{j=0}^{2 \dim(Y)} H^j(Y)$  is *homogeneous* if  $\alpha \in H^j(Y)$  for some  $j$ ; in this case, we take  $|\alpha| = j$ . Let  $\alpha_1, \dots, \alpha_k \in H^*(Y)$  such that every  $\alpha_i$  is homogeneous and

$$\sum_{i=1}^k |\alpha_i| = 2\mathfrak{d}. \tag{2.3}$$

Then, we have the  $k$ -point Gromov-Witten invariant defined by:

$$\langle \alpha_1, \dots, \alpha_k \rangle_{g, \beta} = \int_{[\overline{\mathfrak{M}}_{g,k}(Y, \beta)]^{\text{vir}}} ev_k^*(\alpha_1 \otimes \dots \otimes \alpha_k). \tag{2.4}$$

Next, we summarize certain properties concerning the virtual fundamental class. To begin with, we recall that *the excess dimension* is the difference between the dimension of  $\overline{\mathfrak{M}}_{g,k}(Y, \beta)$  and the expected dimension  $\mathfrak{d}$  in (2.1). Let  $T_Y$  stand for the tangent bundle of  $Y$ . For  $0 \leq i < k$ , we shall use

$$f_{k,i} : \overline{\mathfrak{M}}_{g,k}(Y, \beta) \rightarrow \overline{\mathfrak{M}}_{g,i}(Y, \beta) \tag{2.5}$$

to stand for the forgetful map obtained by forgetting the last  $(k - i)$  marked points and contracting all the unstable components. It is known that  $f_{k,i}$  is flat when  $\beta \neq 0$  and  $0 \leq i < k$ . The following can be found in [LT1, Beh, Get, C-K, LiJ].

**PROPOSITION 2.1.** *Let  $\beta \in H_2(Y; \mathbb{Z})$  and  $\beta \neq 0$ . Let  $e$  be the excess dimension of  $\overline{\mathfrak{M}}_{g,k}(Y, \beta)$ , and  $\mathfrak{M} \subset \overline{\mathfrak{M}}_{g,k}(Y, \beta)$  be a closed substack. Then,*

- (i)  $[\overline{\mathfrak{M}}_{g,k}(Y, \beta)]^{\text{vir}} = (f_{k,0})^*[\overline{\mathfrak{M}}_{g,0}(Y, \beta)]^{\text{vir}}$ ;
- (ii)  $[\overline{\mathfrak{M}}_{g,k}(Y, \beta)]^{\text{vir}}|_{\mathfrak{M}} = c_e((R^1(f_{k+1,k})^*(ev_{k+1})^*T_Y)|_{\mathfrak{M}})$  if there exists an open substack  $\mathfrak{U}$  of  $\overline{\mathfrak{M}}_{g,k}(Y, \beta)$  such that  $\mathfrak{M} \subset \mathfrak{U}$  (i.e,  $\mathfrak{U}$  is an open neighborhood of  $\mathfrak{M}$ ) and  $(R^1(f_{k+1,k})^*(ev_{k+1})^*T_Y)|_{\mathfrak{U}}$  is a rank- $e$  locally free sheaf over  $\mathfrak{U}$ .

We also need one formula for  $g = 0$  known as the composition law. Let  $\{\Delta_a\}$  be a basis of  $H^*(Y)$ , and  $\{\Delta^a\}$  be the basis of  $H^*(Y)$  dual to  $\{\Delta_a\}$  with respect to the intersection pairing of  $Y$ . Let  $\alpha_1, \alpha_2, \alpha_3, \alpha_4 \in H^*(Y)$  be classes of even degrees. Then the combination of (3.3) and (3.6) in [K-M] says that

$$\begin{aligned} & \langle \alpha_1 \alpha_2, \alpha_3, \alpha_4 \rangle_{0, \beta} + \langle \alpha_1, \alpha_2, \alpha_3 \alpha_4 \rangle_{0, \beta} \\ & + \sum_{\beta_1 + \beta_2 = \beta, \beta_1, \beta_2 \neq 0} \sum_a \langle \alpha_1, \alpha_2, \Delta_a \rangle_{0, \beta_1} \langle \Delta^a, \alpha_3, \alpha_4 \rangle_{0, \beta_2} \\ = & \langle \alpha_1 \alpha_3, \alpha_2, \alpha_4 \rangle_{0, \beta} + \langle \alpha_1, \alpha_3, \alpha_2 \alpha_4 \rangle_{0, \beta} \\ & + \sum_{\beta_1 + \beta_2 = \beta, \beta_1, \beta_2 \neq 0} \sum_a \langle \alpha_1, \alpha_3, \Delta_a \rangle_{0, \beta_1} \langle \Delta^a, \alpha_2, \alpha_4 \rangle_{0, \beta_2}. \end{aligned} \tag{2.6}$$

**2.2. Basic facts about the Hilbert scheme of points on a surface.** Let  $X$  be a simply connected smooth projective surface, and  $X^{[n]}$  be the Hilbert scheme of points in  $X$ . An element in  $X^{[n]}$  is represented by a length- $n$  0-dimensional closed subscheme  $\xi$  of  $X$ . For  $\xi \in X^{[n]}$ , let  $I_\xi$  be the corresponding sheaf of ideals. In  $X^{[n]} \times X$ , we have the universal codimension-2 subscheme:

$$\mathcal{Z}_n = \{(\xi, x) \in X^{[n]} \times X \mid x \in \text{Supp}(\xi)\} \subset X^{[n]} \times X. \tag{2.7}$$

Let  $X^{(n)}$  be the  $n$ -th symmetric product of  $X$ . We have the Hilbert-Chow map:

$$\rho : X^{[n]} \rightarrow X^{(n)}. \tag{2.8}$$

For a subset  $Y \subset X$ , we define the subset  $M_n(Y)$  in the Hilbert scheme  $X^{[n]}$ :

$$M_n(Y) = \{\xi \in X^{[n]} \mid \text{Supp}(\xi) \text{ is a point in } Y\} \subset X^{[n]}. \tag{2.9}$$

In particular, for a fixed point  $x \in X$ ,  $M_n(x)$  is just the punctual Hilbert scheme of points on  $X$  at  $x$ . It is known that the punctual Hilbert schemes  $M_n(x)$  are isomorphic for all the surfaces  $X$  and all the points  $x \in X$ .

Let  $\xi \in X^{[n-k]}$  and  $\eta \in X^{[k]}$ . If  $\text{Supp}(\xi) \cap \text{Supp}(\eta) = \emptyset$ , then we use  $\xi + \eta$  to represent the closed subscheme  $\xi \cup \eta$  in  $X^{[n]}$ . Similarly, given a subvariety  $Y$  of  $X^{[n-k]}$  and a point  $\eta \in X^{[k]}$  such that  $\left(\bigcup_{\xi \in Y} \text{Supp}(\xi)\right) \cap \text{Supp}(\eta) = \emptyset$ , we use  $Y + \eta$  to represent the subvariety in  $X^{[n]}$  consisting of all the points  $\xi + \eta$  with  $\xi \in Y$ .

Next, we review some results on homology groups of the Hilbert scheme  $X^{[n]}$  due to Göttsche [Gol], Grojnowski [Gro], and Nakajima [Nak]. Their results say that the space  $\mathbb{H} \stackrel{\text{def}}{=} \bigoplus_{n=0}^{\infty} \bigoplus_{k=0}^{4n} H_k(X^{[n]})$  is an irreducible highest weight representation of the

Heisenberg algebra generated by  $\mathfrak{a}_{-n}(a), n \in \mathbb{Z}, a \in H_*(X) \stackrel{\text{def}}{=} \bigoplus_{k=0}^4 H_k(X)$ . Moreover,

$|0\rangle \stackrel{\text{def}}{=} 1 \in H_0(X^{[0]}; \mathbb{C}) = \mathbb{C}$  is a highest weight vector. It follows that the space  $\mathbb{H}$  is a linear span of elements of the form  $\mathfrak{a}_{-n_1}(a_1) \dots \mathfrak{a}_{-n_k}(a_k)|0\rangle$  where  $k \geq 0, n_1, \dots, n_k > 0$ , and  $a_1, \dots, a_k \in H_*(X)$ . The geometric interpretation of  $\mathfrak{a}_{-n_1}(a_1) \dots \mathfrak{a}_{-n_k}(a_k)|0\rangle$  for homogeneous classes  $a_1, \dots, a_k \in H_*(X)$  can be understood as follows. For  $i = 1, \dots, k$ , let  $a_i \in H_{|a_i|}(X)$  be represented by a cycle  $X_i$  such that  $X_1, \dots, X_k$  are in general position. Then,

$$\mathfrak{a}_{-n_1}(a_1) \dots \mathfrak{a}_{-n_k}(a_k)|0\rangle \in H_m(X^{[n]}) \tag{2.10}$$

where  $n = \sum_{i=1}^k n_i$  and  $m = \sum_{i=1}^k (2n_i - 2 + |a_i|)$ . Up to a scalar,  $\mathbf{a}_{-n_1}(a_1) \dots \mathbf{a}_{-n_k}(a_k)|0\rangle$  is represented by the closure of the real- $\sum_{i=1}^k (2n_i - 2 + |a_i|)$ -dimensional subset:

$$\{\xi_1 + \dots + \xi_k \in X^{[n]} | \xi_i \in M_{n_i}(X_i), \text{Supp}(\xi_i) \cap \text{Supp}(\xi_j) = \emptyset \text{ for } i \neq j\} \quad (2.11)$$

where  $M_{n_i}(X_i)$  is the subset of  $X^{[n_i]}$  defined by (2.9).

DEFINITION 2.2. Let  $x \in X$ , and  $C$  be a real-2-dimensional submanifolds of  $X$ . Then, we define  $\beta_n = \mathbf{a}_{-2}(x)\mathbf{a}_{-1}(x)^{n-2}|0\rangle$ ,  $\beta_C = \mathbf{a}_{-1}(C)\mathbf{a}_{-1}(x)^{n-1}|0\rangle$ , and

$$B_n = \frac{1}{(n-2)!} \mathbf{a}_{-2}(X)\mathbf{a}_{-1}(X)^{n-2}|0\rangle, \quad D_C = \frac{1}{(n-1)!} \mathbf{a}_{-1}(C)\mathbf{a}_{-1}(X)^{n-1}|0\rangle.$$

LEMMA 2.3. Let  $x$  and  $\ell$  be a point and a line in  $X = \mathbb{P}^2$  respectively. Then,

- (i) a basis of  $H_2(X^{[3]}; \mathbb{Z})$  consists of  $\beta_3$  and  $\beta_\ell$ ;
- (ii) a basis of  $H_4(X^{[3]})$  consists of the five homology classes  $\mathbf{a}_{-1}(X)\mathbf{a}_{-1}(x)^2|0\rangle$ ,  $\mathbf{a}_{-2}(\ell)\mathbf{a}_{-1}(x)|0\rangle$ ,  $\mathbf{a}_{-1}(\ell)^2\mathbf{a}_{-1}(x)|0\rangle$ ,  $\mathbf{a}_{-1}(\ell)\mathbf{a}_{-2}(x)|0\rangle$ , and  $\mathbf{a}_{-3}(x)|0\rangle$ ;
- (iii) a basis of  $H_6(X^{[3]})$  consists of the classes  $\mathbf{a}_{-2}(X)\mathbf{a}_{-1}(x)|0\rangle$ ,  $\mathbf{a}_{-1}(X)\mathbf{a}_{-2}(x)|0\rangle$ ,  $\mathbf{a}_{-1}(X)\mathbf{a}_{-1}(\ell)\mathbf{a}_{-1}(x)|0\rangle$ ,  $\mathbf{a}_{-3}(\ell)|0\rangle$ ,  $\mathbf{a}_{-2}(\ell)\mathbf{a}_{-1}(\ell)|0\rangle$ , and  $\mathbf{a}_{-1}(\ell)^3|0\rangle$ ;
- (iv) a basis of  $H_8(X^{[3]})$  consists of the five classes  $\mathbf{a}_{-3}(X)|0\rangle$ ,  $\mathbf{a}_{-2}(X)\mathbf{a}_{-1}(\ell)|0\rangle$ ,  $\mathbf{a}_{-1}(X)\mathbf{a}_{-2}(\ell)|0\rangle$ ,  $\mathbf{a}_{-1}(X)\mathbf{a}_{-1}(\ell)^2|0\rangle$ , and  $\mathbf{a}_{-1}(X)^2\mathbf{a}_{-1}(x)|0\rangle$ ;
- (v) a basis of  $H_{10}(X^{[3]}; \mathbb{Z})$  consists of the divisors  $B_3$  and  $D_\ell$ .

Proof. The proof of (i) and (v) was contained in the proof of the Theorem 4.1 in [LQZ], while the rest statements follow by exploiting (2.10).  $\square$

DEFINITION 2.4. For  $X = \mathbb{P}^2$  and  $i = 2, 4, 6, 8$  and  $10$ , let  $\mathfrak{B}_i$  stand for the linear basis of the homology group  $H_i(X^{[3]})$  given in Lemma 2.3.

Fix  $p \in X^{[3]}$ . Then a basis  $\{\Delta_a\}$  of  $H^*(X^{[3]})$  is given by the Poincaré duals of

$$[p], \mathfrak{B}_i (i = 2, 4, 6, 8, 10), [X^{[3]}] \quad (2.12)$$

where  $[p] = \mathbf{a}_{-1}(x)^3|0\rangle \in H_0(X^{[3]})$  and  $[X^{[3]}] = 1/6 \mathbf{a}_{-1}(X)^3|0\rangle \in H_{12}(X^{[3]})$  are the homology classes corresponding to  $p$  and  $X^{[3]}$  respectively.

The following is the main result proved in [L-Q].

LEMMA 2.5. Let  $d \geq 1$ , and  $x$  and  $\ell$  be a point and a line in  $X = \mathbb{P}^2$  respectively.

- (i) If  $\alpha$  stands for the Poincaré duals of the homology classes  $\mathbf{a}_{-1}(X)\mathbf{a}_{-1}(x)^2|0\rangle$ ,  $\mathbf{a}_{-1}(\ell)^2\mathbf{a}_{-1}(x)|0\rangle$ ,  $\mathbf{a}_{-1}(\ell)\mathbf{a}_{-2}(x)|0\rangle$ , and  $\mathbf{a}_{-3}(x)|0\rangle$ , then  $\langle \alpha \rangle_{0, d\beta_n} = 0$ .
- (ii) If  $\alpha$  is the Poincaré dual of  $\mathbf{a}_{-2}(\ell)\mathbf{a}_{-1}(x)|0\rangle$ , then  $\langle \alpha \rangle_{0, d\beta_n} = 2(K_X \cdot \ell)/d^2$ .

### 2.3. Curves from the punctual Hilbert scheme.

LEMMA 2.6. Fix  $n \geq 2$ . Let  $\text{Hilb}^n(\mathbb{C}^2, 0)$  be the punctual Hilbert scheme of points on  $\mathbb{C}^2$  at the origin, and  $u, v$  be the coordinates of  $\mathbb{C}^2$ . Then,  $H_2(\text{Hilb}^n(\mathbb{C}^2, 0); \mathbb{Z}) \cong \mathbb{Z}$ . Moreover, a generator of  $H_2(\text{Hilb}^n(\mathbb{C}^2, 0); \mathbb{Z})$  is given by

$$\sigma_n = \{(\lambda u + \mu v^{n-1}, u^2, uv, v^n) | \lambda, \mu \in \mathbb{C} \text{ with } |\lambda| + |\mu| \neq 0\}. \quad (2.13)$$

Proof. The first statement was proved in [E-S]. To prove the second statement, following [E-S], take a  $\mathbb{C}^*$ -action on  $\mathbb{C}^2$  given by  $t \cdot (u, v) = (t^{-\alpha}u, t^{-\beta}v)$  with  $\beta \gg \alpha$ .

For  $\xi \in \text{Hilb}^n(\mathbb{C}^2; 0)$ , we use the ideal  $I_\xi \subset \mathbb{C}[u, v]$  to represent  $\xi$ . Then the  $\mathbb{C}^*$ -invariant ideal in  $\mathbb{C}[u, v]$  corresponding to a generator  $\sigma_n$  of  $H_2(\text{Hilb}^n(\mathbb{C}^2, 0); \mathbb{Z})$  is  $(v^{n-1}, uv, u^2)$ . Therefore  $\sigma_n$  is the closure of the cell

$$\begin{aligned} & \{I \in \mathbb{C}[u, v] \mid \ell(\mathbb{C}[u, v]/I) = n, \quad \lim_{t \rightarrow 0}(t \cdot I) = (v^{n-1}, uv, u^2)\} \\ & = \{(v^{n-1} + au, uv, u^2) \mid a \in \mathbb{C}\} \cong \mathbb{C}. \end{aligned}$$

Finally, notice that if  $a \neq 0$ , then  $(v^{n-1} + au, uv, u^2) = (v^{n-1} + au, v^n)$ . So letting  $a \rightarrow \infty$ , we see that the ideal  $(u, v^n)$  is also contained in  $\sigma_n$ . Thus,

$$\sigma_n = \{(v^{n-1} + au, uv, u^2) \mid a \in \mathbb{C}\} \cup \{(u, v^n)\}$$

which is the same as  $\{(\lambda u + \mu v^{n-1}, u^2, uv, v^n) \mid \lambda, \mu \in \mathbb{C} \text{ with } |\lambda| + |\mu| \neq 0\}$ .  $\square$

Let  $R = \mathcal{O}_{\mathbb{C}^2, 0}$  be the local ring of  $\mathbb{C}^2$  at the origin, and  $\mathfrak{m} = (u, v)$  be the maximal ideal of  $R$ . Let  $\eta \in \text{Hilb}^n(\mathbb{C}^2, 0)$ . It is known that there exists an embedding

$$\tau : \text{Hilb}^n(\mathbb{C}^2, 0) \rightarrow \text{Grass}(R/\mathfrak{m}^n, n)$$

where  $R/\mathfrak{m}^n$  is considered as a  $\mathbb{C}$ -vector space of dimension  $\binom{n+1}{2}$ , and  $\tau$  maps an element  $\eta \in \text{Hilb}^n(\mathbb{C}^2, 0)$  to the  $n$ -dimensional quotient of  $R/\mathfrak{m}^n$  in the exact sequence

$$0 \rightarrow I_{\eta, 0}/\mathfrak{m}^n \rightarrow R/\mathfrak{m}^n \rightarrow R/I_{\eta, 0} = \mathcal{O}_{\eta, 0} \rightarrow 0.$$

Let  $\mathfrak{p} : \mathbb{G} \rightarrow \mathbb{P}^{N-1}$  be the Plücker embedding where  $N = \binom{n+1}{2} (\binom{n+1}{2} - n)$ .

LEMMA 2.7. *Identify  $M_n(x)$  with  $\text{Hilb}^n(\mathbb{C}^2, 0)$ , and regard  $\sigma_n$  as a curve in  $M_n(x) \subset X^{[n]}$ . Then as a curve in  $X^{[n]}$ ,  $\sigma_n$  is homologous to  $\beta_n$ .*

*Proof.* According to the results in Sect. 3 of [LQZ], it suffices to show that the image  $(\mathfrak{p} \circ \tau)(\sigma_n)$  is a line. Fix a basis for the  $\mathbb{C}$ -vector space  $R/\mathfrak{m}^n$ :

$$\bar{1}, \bar{u}, \bar{u}^2, \bar{u}\bar{v}, \bar{u}^3, \bar{u}^2\bar{v}, \bar{u}\bar{v}^2, \dots, \bar{u}^{n-1}, \bar{u}^{n-2}\bar{v}, \dots, \bar{u}\bar{v}^{n-2}, \bar{v}, \dots, \bar{v}^{n-1}.$$

Note the special ordering of this basis. Recall from (2.13) that for any  $\eta \in \sigma_n \subset \text{Hilb}^n(\mathbb{C}^2, 0)$ ,  $I_{\eta, 0} = (\lambda u + \mu v^{n-1}, u^2, uv, v^n)$  for some  $\lambda, \mu \in \mathbb{C}$  with  $|\lambda| + |\mu| \neq 0$ . So a basis for the subspace  $I_{\eta, 0}/\mathfrak{m}^n \subset R/\mathfrak{m}^n$  can be chosen as

$$\lambda \bar{u} + \mu \bar{v}^{n-1}, \bar{u}^2, \bar{u}\bar{v}, \bar{u}^3, \bar{u}^2\bar{v}, \bar{u}\bar{v}^2, \dots, \bar{u}^{n-1}, \bar{u}^{n-2}\bar{v}, \dots, \bar{u}\bar{v}^{n-2},$$

and the matrix representation of  $I_{\eta, 0}/\mathfrak{m}^n$  is given by the  $\binom{n}{2} \times \binom{n+1}{2}$ -matrix:

$$\begin{bmatrix} 0 & \lambda & 0 & \dots & 0 & 0 & \dots & 0 & \mu \\ 0 & 0 & 1 & \dots & 0 & 0 & \dots & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \dots & \vdots & \vdots \\ 0 & 0 & 0 & \dots & 1 & 0 & \dots & 0 & 0 \end{bmatrix}. \tag{2.14}$$

Thus,  $(\mathfrak{p} \circ \tau)(\eta) = [0, \dots, 0, \lambda, 0, \dots, 0, \mu, 0, \dots, 0]$  where the positions of  $\lambda$  and  $\mu$  are independent of  $\eta \in \sigma_n$ . So the image  $(\mathfrak{p} \circ \tau)(\sigma_n)$  is a line.  $\square$

Note that the flat limits of the elements  $(\lambda u + v, v^n)$ ,  $\lambda \in \mathbb{C}^*$  in  $\text{Hilb}^n(\mathbb{C}^2, 0)$  as  $\lambda \rightarrow 0$  and  $\lambda \rightarrow \infty$  are equal to  $(v, u^n)$  and  $(u, v^n)$  respectively. So in the punctual Hilbert scheme  $\text{Hilb}^n(\mathbb{C}^2, 0)$ , we have the projective curve:

$$\tilde{\sigma}_n = \{(\lambda u + v, v^n) \mid \lambda \in \mathbb{C}^*\} \cup \{(v, u^n), (u, v^n)\}. \tag{2.15}$$

LEMMA 2.8. *As a curve in  $X^{[n]}$ ,  $\tilde{\sigma}_n$  is homologous to  $\binom{n}{2}\sigma_n$ .*

*Proof.* It suffices to show that  $\tilde{\sigma}_n \sim \binom{n}{2}\sigma_n$  in  $H_2(\text{Hilb}^n(\mathbb{C}^2, 0); \mathbb{Z})$ . By (2.15), if  $\eta \in \tilde{\sigma}_n - \{(v, u^n), (u, v^n)\}$ , then a basis for the subspace  $I_{\eta, 0}/\mathfrak{m}^n \subset R/\mathfrak{m}^n$  is

$$\begin{aligned} &\lambda\bar{u} + \bar{v}, \lambda\bar{u}^2 + \bar{u}\bar{v}, \lambda\bar{u}\bar{v} + \bar{v}^2, \dots, \\ &\lambda\bar{u}^{n-1} + \bar{u}^{n-2}\bar{v}, \lambda\bar{u}^{n-2}\bar{v} + \bar{u}^{n-3}\bar{v}^2, \dots, \lambda\bar{u}\bar{v}^{n-2} + \bar{v}^{n-1}. \end{aligned}$$

As in the proof of Lemma 2.7, we see that the degree of  $(\mathfrak{p} \circ \tau)(\tilde{\sigma}_n - \{(v, u^n), (u, v^n)\})$  is  $\binom{n}{2}$ . So  $(\mathfrak{p} \circ \tau)(\tilde{\sigma}_n)$  has degree  $\binom{n}{2}$ . By Lemma 2.6, there exists an integer  $d$  such that  $\tilde{\sigma}_n \sim d\sigma_n$  in  $H_2(\text{Hilb}^n(\mathbb{C}^2, 0); \mathbb{Z})$ . Since  $(\mathfrak{p} \circ \tau)(\sigma_n)$  is a line,  $d = \binom{n}{2}$ .  $\square$

**3. 3-point genus-0 Gromov-Witten invariants of  $(\mathbb{P}^2)^{[3]}$ .** Let  $X = \mathbb{P}^2$  and  $d \geq 1$ . For simplicity, we shall use  $\langle \alpha_1, \dots, \alpha_k \rangle_{0,d}$  to stand for  $\langle \alpha_1, \dots, \alpha_k \rangle_{0,d\beta_3}$ . Our goal is to compute the 3-point Gromov-Witten invariants  $\langle \alpha_1, \alpha_2, \alpha_3 \rangle_{0,d}$  of  $X^{[3]}$ . Recall from Lemma 2.5 that the 1-point Gromov-Witten invariants  $\langle \alpha_1 \rangle_{0,d}$  of  $X^{[3]}$  have been calculated. Since the expected complex dimension of the stack  $\overline{\mathfrak{M}}_{0,3}(X^{[3]}, d\beta_3)$  is 6, it remains to compute the 2-point Gromov-Witten invariants  $\langle \text{PD}(A_1), \text{PD}(A_2) \rangle_{0,d}$  when  $A_1$  runs over the basis  $\mathfrak{B}_6$  of  $H_6(X^{[3]})$  in Lemma 2.3 (iii) and  $A_2$  runs over the basis  $\mathfrak{B}_8$  of  $H_8(X^{[3]})$  in Lemma 2.3 (iv), and  $\langle \text{PD}(A_1), \text{PD}(A_2), \text{PD}(A_3) \rangle_{0,d}$  when  $A_1, A_2, A_3$  run over the basis  $\mathfrak{B}_8$ .

**3.1.  $\langle \text{PD}(A_1), \text{PD}(A_2) \rangle_{0,d}$  with  $A_1 \in \mathfrak{B}_6$  and  $A_2 \in \mathfrak{B}_8$ .**

LEMMA 3.1. *The 2-point Gromov-Witten invariants  $\langle \text{PD}(A_1), \text{PD}(A_2) \rangle_{0,d}$  are equal to zero for the following pairs of  $(A_1, A_2) \in \mathfrak{B}_6 \times \mathfrak{B}_8$ :*

$$\begin{aligned} &(\mathfrak{a}_{-2}(X)\mathfrak{a}_{-1}(x)|0), (\mathfrak{a}_{-2}(X)\mathfrak{a}_{-1}(\ell)|0)), (\mathfrak{a}_{-1}(X)\mathfrak{a}_{-2}(x)|0), (\mathfrak{a}_{-1}(X)\mathfrak{a}_{-2}(\ell)|0)), \\ &(\mathfrak{a}_{-1}(X)\mathfrak{a}_{-2}(x)|0), (\mathfrak{a}_{-1}(X)\mathfrak{a}_{-1}(\ell)^2|0)), (\mathfrak{a}_{-1}(X)\mathfrak{a}_{-1}(\ell)\mathfrak{a}_{-1}(x)|0), (\mathfrak{a}_{-3}(X)), \\ &(\mathfrak{a}_{-1}(X)\mathfrak{a}_{-1}(\ell)\mathfrak{a}_{-1}(x)|0), (\mathfrak{a}_{-1}(X)\mathfrak{a}_{-1}(\ell)^2|0)), \\ &(\mathfrak{a}_{-1}(X)\mathfrak{a}_{-1}(\ell)\mathfrak{a}_{-1}(x)|0), (\mathfrak{a}_{-1}(X)^2\mathfrak{a}_{-1}(x)|0)), (\mathfrak{a}_{-3}(\ell)|0), (\mathfrak{a}_{-1}(X)\mathfrak{a}_{-1}(\ell)^2|0)), \\ &(\mathfrak{a}_{-3}(\ell)|0), (\mathfrak{a}_{-1}(X)^2\mathfrak{a}_{-1}(x)|0)), (\mathfrak{a}_{-2}(\ell)\mathfrak{a}_{-1}(\ell)|0), (\mathfrak{a}_{-1}(X)^2\mathfrak{a}_{-1}(x)|0)), \\ &(\mathfrak{a}_{-1}(\ell)^3|0), (\mathfrak{a}_{-3}(X)), (\mathfrak{a}_{-1}(\ell)^3|0), (\mathfrak{a}_{-1}(X)\mathfrak{a}_{-2}(\ell)|0)), \\ &(\mathfrak{a}_{-1}(\ell)^3|0), (\mathfrak{a}_{-1}(X)\mathfrak{a}_{-1}(\ell)^2|0)), (\mathfrak{a}_{-1}(\ell)^3|0), (\mathfrak{a}_{-1}(X)^2\mathfrak{a}_{-1}(x)|0)). \end{aligned}$$

*Proof.* These follow from similar geometric arguments. For instance, let us show that  $\langle \text{PD}(A_1), \text{PD}(A_2) \rangle_{0,d} = 0$  when  $A_1 = \mathfrak{a}_{-1}(\ell)^3|0$  and  $A_2 = \mathfrak{a}_{-1}(X)\mathfrak{a}_{-1}(\ell)^2|0$ .

Choose five lines  $\ell_1, \dots, \ell_5 \subset X = \mathbb{P}^2$  in general position. By (2.11), we see that up to a scalar,  $A_1$  is represented by the closure of the subset

$$\{x_1 + x_2 + x_3 \mid x_1, x_2, x_3 \text{ are distinct and } x_i \in \ell_i \text{ for each } i\}. \tag{3.1}$$

Similarly,  $A_2$  is represented by the closure of the subset

$$\{x + x_4 + x_5 \mid x, x_4, x_5 \text{ are distinct and } x_i \in \ell_i \text{ for each } i\}. \tag{3.2}$$

Let  $\mathfrak{M}$  be the substack of  $\overline{\mathfrak{M}}_{0,2}(X^{[3]}, d\beta_3)$  parametrizing all the stable maps  $[\mu : (C; p_1, p_2) \rightarrow X^{[3]}]$  with  $\mu(p_1) \in A_1$  and  $\mu(p_2) \in A_2$ . We claim that  $\mathfrak{M} = \emptyset$ . Indeed, assume  $[\mu : (C; p_1, p_2) \rightarrow X^{[3]}]$  is an object of  $\mathfrak{M}$ . On one hand, by (3.1),  $\rho(\mu(C)) = 2(\ell_i \cap \ell_j) + x_k$  where  $\rho$  is the Hilbert-Chow map (2.8),  $\{i, j, k\}$  is a permutation of  $\{1, 2, 3\}$ , and  $x_k \in \ell_k$ . On the other hand, by (3.2), we obtain

$$\rho(\mu(C)) = 2(\ell_4 \cap \ell_5) + x$$

for some  $x \in X$ , or  $\rho(\mu(C)) = 2x_i + x_j$  where  $\{i, j\}$  is a permutation of  $\{4, 5\}$ ,  $x_i \in \ell_i$ , and  $x_j \in \ell_j$ . Since the lines  $\ell_1, \dots, \ell_5 \subset X = \mathbb{P}^2$  are in general position, such  $\rho(\mu(C))$  does not exist. So  $\mathfrak{M} = \emptyset$ . Hence  $\langle \text{PD}(A_1), \text{PD}(A_2) \rangle_{0,d} = 0$ .  $\square$

LEMMA 3.2. *The 2-point Gromov-Witten invariants  $\langle \text{PD}(A_1), \text{PD}(A_2) \rangle_{0,d}$  are equal to zero for the following pairs of  $(A_1, A_2) \in \mathfrak{B}_6 \times \mathfrak{B}_8$ :*

$$\begin{aligned} & (\mathfrak{a}_{-2}(X)\mathfrak{a}_{-1}(x)|0\rangle, \mathfrak{a}_{-3}(X)|0\rangle), (\mathfrak{a}_{-2}(X)\mathfrak{a}_{-1}(x)|0\rangle, \mathfrak{a}_{-1}(X)\mathfrak{a}_{-1}(\ell)^2|0\rangle), \\ & (\mathfrak{a}_{-2}(X)\mathfrak{a}_{-1}(x)|0\rangle, \mathfrak{a}_{-1}(X)^2\mathfrak{a}_{-1}(x)|0\rangle), (\mathfrak{a}_{-1}(X)\mathfrak{a}_{-2}(x)|0\rangle, \mathfrak{a}_{-3}(X)|0\rangle), \\ & (\mathfrak{a}_{-1}(X)\mathfrak{a}_{-2}(x)|0\rangle, \mathfrak{a}_{-1}(X)^2\mathfrak{a}_{-1}(x)|0\rangle), (\mathfrak{a}_{-1}(X)\mathfrak{a}_{-1}(\ell)\mathfrak{a}_{-1}(x)|0\rangle, \mathfrak{a}_{-2}(X)\mathfrak{a}_{-1}(\ell)|0\rangle), \\ & (\mathfrak{a}_{-1}(X)\mathfrak{a}_{-1}(\ell)\mathfrak{a}_{-1}(x)|0\rangle, \mathfrak{a}_{-1}(X)\mathfrak{a}_{-2}(\ell)|0\rangle), (\mathfrak{a}_{-3}(\ell)|0\rangle, \mathfrak{a}_{-2}(X)\mathfrak{a}_{-1}(\ell)|0\rangle), \\ & (\mathfrak{a}_{-3}(\ell)|0\rangle, \mathfrak{a}_{-1}(X)\mathfrak{a}_{-2}(\ell)|0\rangle), (\mathfrak{a}_{-2}(\ell)\mathfrak{a}_{-1}(\ell)|0\rangle, \mathfrak{a}_{-3}(X)|0\rangle), \\ & (\mathfrak{a}_{-2}(\ell)\mathfrak{a}_{-1}(\ell)|0\rangle, \mathfrak{a}_{-1}(X)\mathfrak{a}_{-1}(\ell)^2|0\rangle), (\mathfrak{a}_{-1}(\ell)^3|0\rangle, \mathfrak{a}_{-2}(X)\mathfrak{a}_{-1}(\ell)|0\rangle). \end{aligned}$$

*Proof.* These invariants are equal to certain genus-0 Gromov-Witten invariants of a K3 surface. So our lemma follows from the fact that all the genus-0 Gromov-Witten invariants of a K3 surface are equal to zero. For instance, let us show that  $\langle \text{PD}(A_1), \text{PD}(A_2) \rangle_{0,d} = 0$  when  $A_1 = \mathfrak{a}_{-2}(X)\mathfrak{a}_{-1}(x)|0\rangle$  and  $A_2 = \mathfrak{a}_{-3}(X)|0\rangle$ .

Fix  $x \in X$ , and a small analytic open subset  $U$  of  $X$  such that  $x \in U$ . We may assume that  $U$  is independent of  $X$ . Note that for a stable map  $[\mu : (C; p_1, p_2) \rightarrow X^{[3]}] \in \overline{\mathfrak{M}}_{0,2}(X^{[3]}, d\beta_3)$ , either  $\mu(C) \subset U^{[3]}$  or  $\mu(C) \cap U^{[3]} = \emptyset$ . So the analytic open substack  $\mathfrak{U} \subset \overline{\mathfrak{M}}_{0,2}(X^{[3]}, d\beta_3)$  parametrizing all stable maps  $[\mu : (C; p_1, p_2) \rightarrow X^{[3]}]$  with  $\mu(C) \subset U^{[3]}$  depends only on  $U$ , and is independent of  $X$ .

Let  $\mathfrak{M}$  be the substack of  $\overline{\mathfrak{M}}_{0,2}(X^{[3]}, d\beta_3)$  parametrizing all the stable maps  $[\mu : (C; p_1, p_2) \rightarrow X^{[3]}]$  such that  $\mu(p_1) \in A_1$  and  $\mu(p_2) \in A_2$ . Note from the descriptions of  $A_1$  and  $A_2$  that if  $[\mu : (C; p_1, p_2) \rightarrow X^{[3]}] \in \mathfrak{M}$ , then  $\mu(C) \subset M_3(x) \subset U^{[3]}$ . So  $\mathfrak{M} \subset \mathfrak{U}$ . In fact,  $\mathfrak{M}$  parametrizes all the stable maps  $[\mu : (C; p_1, p_2) \rightarrow X^{[3]}] \in \mathfrak{U}$  with  $\mu(C) \subset M_3(x) \subset U^{[3]}$ . So  $\mathfrak{M}$  is also independent of  $X$ .

In summary, we showed that  $\mathfrak{M} \subset \mathfrak{U}$  where  $\mathfrak{U}$  is analytic open in  $\overline{\mathfrak{M}}_{0,2}(X^{[3]}, d\beta_3)$ , and  $\mathfrak{M}$  and  $\mathfrak{U}$  are independent of  $X$ . It follows from the constructions of the virtual fundamental class (see [LT2, LT3, Ru1]) that the restriction  $[\overline{\mathfrak{M}}_{0,2}(X^{[3]}, d\beta_3)]^{\text{vir}}|_{\mathfrak{M}}$  is independent of the smooth surface  $X$ . So we have  $\langle \text{PD}(A_1), \text{PD}(A_2) \rangle_{0,d} = \langle \text{PD}(A'_1), \text{PD}(A'_2) \rangle_{0,d}$  where  $A'_1 = \mathfrak{a}_{-2}(X')\mathfrak{a}_{-1}(x')|0\rangle$ ,  $A'_2 = \mathfrak{a}_{-3}(X')|0\rangle$ ,  $x' \in X'$ , and  $X'$  is a K3 surface. Therefore, we conclude that  $\langle \text{PD}(A_1), \text{PD}(A_2) \rangle_{0,d} = 0$ .  $\square$

To compute other 2-point invariants  $\langle \text{PD}(A_1), \text{PD}(A_2) \rangle_{0,d}$ , we recall from [L-Q] some results concerning obstruction bundles and virtual fundamental classes. Fix  $n \geq 2$ . Let  $B_* = \{\xi \in X^{[n]} \mid |\text{Supp}(\xi)| = n - 1\}$  and  $X_{s*}^{(n)} = \rho(B_*)$  where  $\rho$  is the Hilbert-Chow map. Let  $j_2 : X_{s*}^{(n)} \rightarrow X$  be the morphism defined by sending  $2x + x_3 + \dots + x_n$  to  $x$ . For  $k \geq 0$ , let  $\mathfrak{U}_k$  be the open substack of  $\overline{\mathfrak{M}}_{0,k}(X^{[n]}, d\beta_n)$  parametrizing stable maps  $[\mu : (C; p_1, \dots, p_k) \rightarrow X^{[n]}]$  such that  $\mu(C) \subset B_*$ . For  $k \geq 1$ , note that  $\mathfrak{U}_k = f_{k,0}^{-1}(\mathfrak{U}_0)$ . Put  $\tilde{e}v_k = ev_k|_{\mathfrak{U}_k}$  and  $\tilde{f}_{k,0} = f_{k,0}|_{\mathfrak{U}_k}$ . Then we can regard  $\tilde{e}v_k$  and  $\tilde{f}_{k,0}$  as morphisms from  $\mathfrak{U}_k$  to  $(B_*)^k$  and  $\mathfrak{U}_0$  respectively. In addition, there exist morphisms  $\phi$  and  $j_1$  forming a commutative diagram:

$$\begin{array}{ccccc} \mathfrak{U}_1 & \xrightarrow{\tilde{e}v_1} & B_* & \xrightarrow{j_1} & \mathbb{P}(j_2^* T_X^*) \\ \downarrow \tilde{f}_{1,0} & & \downarrow \rho & & \downarrow \pi \\ \mathfrak{U}_0 & \xrightarrow{\phi} & \rho(B_*) & = & X_{s*}^{(n)} \xrightarrow{j_2} X \end{array} \tag{3.3}$$

where  $\pi: \mathbb{P}(j_2^*T_X^*) \rightarrow X_{s^*}^{(n)}$  is the natural projection of the  $\mathbb{P}^1$ -bundle. By the Lemma 3.1 in [L-Q], the restriction of  $R^1(f_{1,0})_*(ev_1^*T_{X^{[n]}})$  to  $\mathfrak{U}_0$  is a locally free sheaf of rank  $(2d - 1)$ . Since the excess dimension of  $\mathfrak{U}_0$  is  $(2d - 1)$ , Proposition 2.1 implies that if  $\mathfrak{M}$  is a closed substack of  $\overline{\mathfrak{M}}_{0,k}(X^{[n]}, d\beta_n)$  contained in  $\mathfrak{U}_k$ , then

$$[\overline{\mathfrak{M}}_{0,k}(X^{[n]}, d\beta_n)]^{vir}|_{\mathfrak{M}} = \left\{ \tilde{f}_{k,0}^*(c_{2d-1}(R^1(f_{1,0})_*(ev_1)^*T_{X^{[n]}})|_{f_{k,0}(\mathfrak{M})}) \right\} |_{\mathfrak{M}}. \tag{3.4}$$

The following summarizes the formula (32), Lemma 3.2 and Remark 3.1 in [L-Q].

LEMMA 3.3.

- (i)  $\mathcal{O}_{B_*}(B_*) \cong j_1^*\mathcal{O}_{\mathbb{P}(j_2^*T_X^*)}(-2)$ .
- (ii) Let  $\mathcal{V}$  denote the restriction of  $R^1(f_{1,0})_*(ev_1)^*T_{X^{[n]}}$  to  $\mathfrak{U}_0$ . Then, the locally free sheaf  $\mathcal{V}$  sits in the exact sequence

$$0 \rightarrow (j_2 \circ \phi)^*\mathcal{O}_X(-K_X) \rightarrow \mathcal{V} \rightarrow \mathcal{E} \rightarrow 0$$

where  $\mathcal{E} = R^1(\tilde{f}_{1,0})_*(j_1 \circ \tilde{ev}_1)^*((j_2 \circ \pi)^*T_X \otimes \mathcal{O}_{\mathbb{P}(j_2^*T_X^*)}(-1))$ .

- (iii) Over  $\phi^{-1}(2x_2 + x_3 + \dots + x_n) \cong \overline{\mathfrak{M}}_{0,0}(\mathbb{P}^1, d[\mathbb{P}^1])$  where  $x_2, \dots, x_n$  are distinct points in  $X$ , there is an isomorphism of locally free sheaves:

$$\mathcal{E}|_{\phi^{-1}(2x_2+x_3+\dots+x_n)} \cong R^1(f_{1,0})_*(ev_1)^*(\mathcal{O}_{\mathbb{P}^1}(-1) \oplus \mathcal{O}_{\mathbb{P}^1}(-1)).$$

Next, using Lemma 3.3, we compute other 2-point Gromov-Witten invariants.

LEMMA 3.4. Let  $X = \mathbb{P}^2$  and  $d \geq 1$ . Then,

- (i)  $\langle \text{PD}(A_1), \text{PD}(A_2) \rangle_{0,d} = 0$  for the two choices of  $(A_1, A_2)$ :
 
$$(\mathfrak{a}_{-1}(X)\mathfrak{a}_{-2}(x)|0, \mathfrak{a}_{-2}(X)\mathfrak{a}_{-1}(\ell)|0), (\mathfrak{a}_{-2}(\ell)\mathfrak{a}_{-1}(\ell)|0, \mathfrak{a}_{-1}(X)\mathfrak{a}_{-2}(\ell)|0);$$
- (ii)  $\langle \text{PD}(A_1), \text{PD}(A_2) \rangle_{0,d} = -4(K_X \cdot \ell)/d$  for the two choices of  $(A_1, A_2)$ :
 
$$(\mathfrak{a}_{-2}(X)\mathfrak{a}_{-1}(x)|0, \mathfrak{a}_{-1}(X)\mathfrak{a}_{-2}(\ell)|0), (\mathfrak{a}_{-2}(\ell)\mathfrak{a}_{-1}(\ell)|0, \mathfrak{a}_{-2}(X)\mathfrak{a}_{-1}(\ell)|0).$$

*Proof.* (i) Since the proofs for the two choices of  $(A_1, A_2)$  are similar, we only prove  $\langle \text{PD}(A_1), \text{PD}(A_2) \rangle_{0,d} = 0$  for  $A_1 = \mathfrak{a}_{-1}(X)\mathfrak{a}_{-2}(x)|0$  and  $A_2 = \mathfrak{a}_{-2}(X)\mathfrak{a}_{-1}(\ell)|0$ . Fix a point  $x$  and a line  $\ell$  in  $X = \mathbb{P}^2$  such that  $x \notin \ell$ . By (2.11), we see that up to a scalar,  $A_1$  is represented by the closure of the subset

$$\{x' + \xi \mid \xi \in M_2(x) \text{ and } x' \neq x\}. \tag{3.5}$$

Similarly,  $A_2$  is represented by the closure of the subset

$$\{\xi + x_1 \mid x_1 \in \ell, \xi \in M_2(x_2) \text{ for some } x_2 \notin \ell\}. \tag{3.6}$$

Working with algebraic cycles instead of cohomology classes, we have

$$\langle \text{PD}(A_1), \text{PD}(A_2) \rangle_{0,d} = [\overline{\mathfrak{M}}_{0,2}(X^{[3]}, d\beta_3)]^{vir} \cdot ev_2^*[A_1 \times A_2]. \tag{3.7}$$

Note that  $ev_2^*[A_1 \times A_2]$  is an algebraic cycle supported in  $ev_2^{-1}(A_1 \times A_2)$ . By (3.5) and (3.6),  $ev_2^{-1}(A_1 \times A_2)$  parametrizes all the stable maps  $[\mu : (C; p_1, p_2) \rightarrow X^{[3]}]$  satisfying  $\rho(\mu(C)) \in 2x + \ell$ . In particular,  $ev_2^{-1}(A_1 \times A_2) \subset \mathfrak{U}_2$ . Applying (3.4) to  $\mathfrak{M} = ev_2^{-1}(A_1 \times A_2)$  and combining with Lemma 3.3 (ii), we obtain

$$\begin{aligned} [\overline{\mathfrak{M}}_{0,2}(X^{[3]}, d\beta_3)]^{vir}|_{\mathfrak{M}} &= \left\{ \tilde{f}_{2,0}^*(c_{2d-1}(R^1(f_{1,0})_*(ev_1)^*T_{X^{[n]}})|_{f_{2,0}(\mathfrak{M})}) \right\} |_{\mathfrak{M}} \\ &= \left\{ \tilde{f}_{2,0}^*((j_2 \circ \phi)^*(-K_X) \cdot c_{2d-2}(\mathcal{E})|_{f_{2,0}(\mathfrak{M})}) \right\} |_{\mathfrak{M}}. \end{aligned} \tag{3.8}$$

Now  $(j_2 \circ \phi)^*(-K_X) = 3(j_2 \circ \phi)^*[\ell']$  where the line  $\ell'$  in  $X = \mathbb{P}^2$  is chosen not to contain the fixed point  $x$ . We have  $(j_2 \circ \phi)^{-1}(\ell') \cap f_{2,0}(\mathfrak{M}) = \emptyset$ . Therefore,  $(j_2 \circ \phi)^*(-K_X)|_{f_{2,0}(\mathfrak{M})} = 0$ . By (3.8),  $[\overline{\mathfrak{M}}_{0,2}(X^{[3]}, d\beta_3)]^{\text{vir}}|_{\mathfrak{M}} = 0$ . Since  $ev_2^*[A_1 \times A_2]$  is supported in  $\mathfrak{M} = ev_2^{-1}(A_1 \times A_2)$ , we see from (3.7) that  $\langle PD(A_1), PD(A_2) \rangle_{0,d} = 0$ .

(ii) Again, the proofs for the two choices of  $(A_1, A_2)$  are similar. So we only prove  $\langle PD(A_1), PD(A_2) \rangle_{0,d} = -4(K_X \cdot \ell)/d$  for  $A_1 = \mathfrak{a}_{-2}(\ell)\mathfrak{a}_{-1}(\ell)|0\rangle$  and  $A_2 = \mathfrak{a}_{-2}(X)\mathfrak{a}_{-1}(\ell)|0\rangle$ . We follow the argument for the Lemma 3.3 (ii) in [L-Q].

Fix three lines  $\ell_1, \ell_2, \ell_3 \subset X = \mathbb{P}^2$  in general position. Then  $A_1$  is represented by the closure of the subset  $\{\xi + x \mid \xi \in M_2(\ell_1), x \in \ell_2, x \notin |\text{Supp}(\xi)|\}$ . Similarly,  $A_2$  is represented by the closure of the subset

$$\{\xi + x \mid \xi \in M_2(X), x \in \ell_3, x \notin |\text{Supp}(\xi)|\}.$$

So  $ev_2^{-1}(A_1 \times A_2)$  parametrizes all the stable maps  $[\mu : (C; p_1, p_2) \rightarrow X^{[3]}]$  satisfying  $\rho(\mu(C)) \in 2\ell_1 + (\ell_2 \cap \ell_3) \subset B_*$ , and  $ev_2^*[A_1 \times A_2]$  is a cycle in  $ev_2^{-1}(A_1 \times A_2) \subset \mathfrak{U}_2$ . As in (3.7) and (3.8), we see that  $\langle PD(A_1), PD(A_2) \rangle_{0,d}$  is equal to

$$\tilde{f}_{2,0}^*((j_2 \circ \phi)^*(-K_X) \cdot c_{2d-2}(\mathcal{E})) ev_2^*[A_1 \times A_2].$$

Since  $\tilde{f}_{2,0}^*((j_2 \circ \phi)^*(-K_X) \cdot c_{2d-2}(\mathcal{E}))$  is supported in  $\mathfrak{U}_2$ , recalling the definition of  $\tilde{ev}_2$  from the paragraph containing (3.3), we see that  $\langle PD(A_1), PD(A_2) \rangle_{0,d}$  equals

$$\tilde{f}_{2,0}^*((j_2 \circ \phi)^*(-K_X) \cdot c_{2d-2}(\mathcal{E})) \tilde{ev}_2^*([A_1][B_*] \times [A_2][B_*]).$$

Now,  $[A_i][B_*] = [A_i \cap B_*]c_1(\mathcal{O}_{B_*}(B_*))$ . Let  $\mathbb{D}$  stand for the first Chern class of the tautological line bundle over  $B_* \cong \mathbb{P}(j_2^*T_X^*)$ . Then we obtain from Lemma 3.3 (i) that the invariant  $\langle PD(A_1), PD(A_2) \rangle_{0,d}$  is equal to

$$4\tilde{f}_{2,0}^*((j_2 \circ \phi)^*(-K_X) \cdot c_{2d-2}(\mathcal{E})) \cdot \tilde{ev}_2^*([A_1 \cap B_*]\mathbb{D} \times [A_2 \cap B_*]\mathbb{D}). \tag{3.9}$$

Fix a line  $\ell$  such that  $\ell_1, \ell_2, \ell_3, \ell$  are in general position. We claim that

$$\tilde{f}_{2,0}^*(j_2 \circ \phi)^*[\ell] \cdot \tilde{ev}_2^*([A_1 \cap B_*]\mathbb{D} \times [A_2 \cap B_*]\mathbb{D}) = [\tilde{ev}_2^{-1}(\xi_1 \times \xi_2)] \tag{3.10}$$

where  $\xi_1$  and  $\xi_2$  are two fixed points in  $M_2(x_1) + x_2$  with  $\{x_1\} = \ell_1 \cap \ell$ , and  $\{x_2\} = \ell_2 \cap \ell_3$ . To see this, let  $\tilde{e}_1$  and  $\tilde{e}_2$  be the restrictions to  $\mathfrak{U}_2$  of the two evaluation maps from  $\overline{\mathfrak{M}}_{0,2}(X^{[3]}, d\beta_3)$  to  $X^{[3]}$ . We regard  $\tilde{e}_1$  and  $\tilde{e}_2$  as morphisms from  $\mathfrak{U}_2$  to  $B_*$ . Then,  $\tilde{ev}_2 = \tilde{e}_1 \times \tilde{e}_2$  and  $\phi \circ \tilde{f}_{2,0} = \rho \circ \tilde{e}_1$ . So

$$\begin{aligned} & \tilde{f}_{2,0}^*(j_2 \circ \phi)^*[\ell] \cdot \tilde{ev}_2^*([A_1 \cap B_*]\mathbb{D} \times [A_2 \cap B_*]\mathbb{D}) \\ &= \tilde{f}_{2,0}^*(j_2 \circ \phi)^*[\ell] \cdot \tilde{e}_1^*([A_1 \cap B_*]\mathbb{D}) \cdot \tilde{e}_2^*([A_2 \cap B_*]\mathbb{D}) \\ &= \tilde{e}_1^*((j_2 \circ \rho)^*[\ell] \cdot [A_1 \cap B_*] \cdot \mathbb{D}) \cdot \tilde{e}_2^*([A_2 \cap B_*]\mathbb{D}). \end{aligned}$$

Now the cycle  $(j_2 \circ \rho)^*[\ell] \cdot [A_1 \cap B_*] \cdot \mathbb{D}$  is represented by  $\eta_1 + \ell_2$  where  $\eta_1$  is a fixed point in  $M_2(x_1)$ . So  $\tilde{e}_1^*((j_2 \circ \rho)^*[\ell] \cdot [A_1 \cap B_*] \cdot \mathbb{D})$  is represented by the substack  $\mathfrak{M}_2$  of  $\overline{\mathfrak{M}}_{0,2}(X^{[3]}, d\beta_3)$  parametrizing all the stable maps  $[\mu : (C; p_1, p_2) \rightarrow X^{[3]}]$  such that  $\mu(C) = M_2(x_1) + x$  for some  $x \in \ell_2$  and  $\mu(p_1) = \eta_1 + x$ . It follows that

$$\begin{aligned} & \tilde{f}_{2,0}^*(j_2 \circ \phi)^*[\ell] \cdot \tilde{ev}_2^*([A_1 \cap B_*]\mathbb{D} \times [A_2 \cap B_*]\mathbb{D}) \\ &= [\mathfrak{M}_2] \cdot \tilde{e}_2^*([A_2 \cap B_*]\mathbb{D}) = [\tilde{ev}_2^{-1}(\xi_1 \times \xi_2)] \end{aligned}$$

where  $\xi_1 = \eta_1 + x_2$  and  $\xi_2$  is a fixed point in  $M_2(x_1) + x_2$ . This proves (3.10).

By (3.9) and (3.10),  $\langle \text{PD}(A_1), \text{PD}(A_2) \rangle_{0,d}$  is equal to

$$\begin{aligned} & 12\tilde{f}_{2,0}^*(c_{2d-2}(\mathcal{E})) \cdot [\tilde{e}v_2^{-1}(\xi_1 \times \xi_2)] \\ &= -4(K_X \cdot \ell) \cdot c_{2d-2}(\mathcal{E}) \cdot (\tilde{f}_{2,0})_*[\tilde{e}v_2^{-1}(\xi_1 \times \xi_2)]. \end{aligned} \tag{3.11}$$

Note that  $\tilde{e}v_2^{-1}(\xi_1 \times \xi_2)$  parametrizes all the stable maps  $[\mu : (C; p_1, p_2) \rightarrow X^{[3]}]$  in  $\overline{\mathcal{M}}_{0,2}(X^{[3]}, d\beta_3)$  satisfying  $\mu(p_1) = \xi_1$  and  $\mu(p_2) = \xi_2$ . For these stable maps, we must have  $\mu(C) = M_2(x_1) + x_2$ . So the restriction of  $\tilde{f}_{2,0}$  to  $\tilde{e}v_2^{-1}(\xi_1 \times \xi_2)$  is a degree- $d^2$  morphism to  $\phi^{-1}(2x_1 + x_2)$ . Thus,  $(\tilde{f}_{2,0})_*[\tilde{e}v_2^{-1}(\xi_1 \times \xi_2)] = d^2[\phi^{-1}(2x_1 + x_2)]$ . By (3.11), we obtain  $\langle \text{PD}(A_1), \text{PD}(A_2) \rangle_{0,d} = -4(K_X \cdot \ell)d^2 \cdot c_{2d-2}(\mathcal{E}|_{\phi^{-1}(2x_1+x_2)})$ . By Lemma 3.3 (iii) and the Theorem 9.2.3 in [C-K],  $c_{2d-2}(\mathcal{E}|_{\phi^{-1}(2x_1+x_2)}) = 1/d^3$ . Therefore, we have  $\langle \text{PD}(A_1), \text{PD}(A_2) \rangle_{0,d} = -4(K_X \cdot \ell)/d$ .  $\square$

In view of Lemma 3.1, Lemma 3.2 and Lemma 3.4, the only 2-point Gromov-Witten invariant  $\langle \text{PD}(A_1), \text{PD}(A_2) \rangle_{0,d}$  with  $A_1 \in \mathfrak{B}_6$  and  $A_2 \in \mathfrak{B}_8$  that has not been computed is when  $A_1 = \mathfrak{a}_{-3}(\ell)|0\rangle$  and  $A_2 = \mathfrak{a}_{-3}(X)|0\rangle$ . This invariant

$$\langle \text{PD}(\mathfrak{a}_{-3}(\ell)|0\rangle), \text{PD}(\mathfrak{a}_{-3}(X)|0\rangle) \rangle_{0,d} \tag{3.12}$$

will be studied in Sect. 4 by using the localization formula.

We summarize the results in this subsection into a theorem.

**THEOREM 3.5.** *Let  $X = \mathbb{P}^2$ , and  $\mathfrak{B}_6$  and  $\mathfrak{B}_8$  be defined in Definition 2.4. Let  $d \geq 1$ ,  $A_1 \in \mathfrak{B}_6$  and  $A_2 \in \mathfrak{B}_8$ . Let  $x, \ell$  be a point and a line in  $X$  respectively. Then,  $\langle \text{PD}(A_1), \text{PD}(A_2) \rangle_{0,d}$  is zero unless the pair  $(A_1, A_2)$  is one of the following:*

- (i)  $(\mathfrak{a}_{-2}(X)\mathfrak{a}_{-1}(x)|0\rangle, \mathfrak{a}_{-1}(X)\mathfrak{a}_{-2}(\ell)|0\rangle)$
- (ii)  $(\mathfrak{a}_{-2}(\ell)\mathfrak{a}_{-1}(\ell)|0\rangle, \mathfrak{a}_{-2}(X)\mathfrak{a}_{-1}(\ell)|0\rangle)$
- (iii)  $(\mathfrak{a}_{-3}(\ell)|0\rangle, \mathfrak{a}_{-3}(X)|0\rangle)$ .

Moreover,  $\langle \text{PD}(A_1), \text{PD}(A_2) \rangle_{0,d} = 12/d$  in cases (i) and (ii).  $\square$

**3.2.  $\langle \text{PD}(A_1), \text{PD}(A_2), \text{PD}(A_3) \rangle_{0,d}$  with  $A_1, A_2, A_3 \in \mathfrak{B}_8$ .**

**LEMMA 3.6.** *The Gromov-Witten invariants  $\langle \text{PD}(A_1), \text{PD}(A_2), \text{PD}(A_3) \rangle_{0,d}$  are equal to zero for the following triples of  $(A_1, A_2, A_3) \in (\mathfrak{B}_8)^3$ :*

$$\begin{aligned} & A_1 = \mathfrak{a}_{-3}(X)|0\rangle, A_2 \neq \mathfrak{a}_{-3}(X)|0\rangle, A_3 \neq \mathfrak{a}_{-3}(X)|0\rangle, \\ & A_1 = A_2 = \mathfrak{a}_{-1}(X)\mathfrak{a}_{-1}(\ell)^2|0\rangle, A_3 \text{ arbitrary}, \\ & A_1 = \mathfrak{a}_{-1}(X)^2\mathfrak{a}_{-1}(x)|0\rangle, A_2 \text{ arbitrary}, A_3 \text{ arbitrary}, \\ & (\mathfrak{a}_{-3}(X)|0\rangle, \mathfrak{a}_{-3}(X)|0\rangle, \mathfrak{a}_{-1}(X)\mathfrak{a}_{-1}(\ell)^2|0\rangle), \\ & A_1 = A_2 = \mathfrak{a}_{-2}(X)\mathfrak{a}_{-1}(\ell)|0\rangle, A_3 \neq \mathfrak{a}_{-1}(X)\mathfrak{a}_{-2}(\ell)|0\rangle, \\ & (\mathfrak{a}_{-2}(X)\mathfrak{a}_{-1}(\ell)|0\rangle, \mathfrak{a}_{-1}(X)\mathfrak{a}_{-2}(\ell)|0\rangle, \mathfrak{a}_{-1}(X)\mathfrak{a}_{-1}(\ell)^2|0\rangle), \\ & A_1, A_2, A_3 \in \{\mathfrak{a}_{-1}(X)\mathfrak{a}_{-2}(\ell)|0\rangle, \mathfrak{a}_{-1}(X)\mathfrak{a}_{-1}(\ell)^2|0\rangle\}. \end{aligned}$$

*Proof.* The arguments are similar to those for Lemma 3.1 and Lemma 3.2.  $\square$

**LEMMA 3.7.** *Let  $X = \mathbb{P}^2$ ,  $\ell \subset X$  be a line, and  $d \geq 1$ . Then,*

- (i)  $\langle \text{PD}(A_1), \text{PD}(A_2), \text{PD}(A_3) \rangle_{0,d} = 0$  for the following triple:

$$(A_1, A_2, A_3) = (\mathfrak{a}_{-2}(X)\mathfrak{a}_{-1}(\ell)|0\rangle, \mathfrak{a}_{-1}(X)\mathfrak{a}_{-2}(\ell)|0\rangle, \mathfrak{a}_{-1}(X)\mathfrak{a}_{-2}(\ell)|0\rangle);$$

(ii)  $\langle \text{PD}(A_1), \text{PD}(A_2), \text{PD}(A_3) \rangle_{0,d} = 8(K_X \cdot \ell)$  for the triple:

$$(A_1, A_2, A_3) = (\mathfrak{a}_{-2}(X)\mathfrak{a}_{-1}(\ell)|0), \mathfrak{a}_{-2}(X)\mathfrak{a}_{-1}(\ell)|0, \mathfrak{a}_{-1}(X)\mathfrak{a}_{-2}(\ell)|0).$$

*Proof.* The arguments are similar to those for Lemma 3.4 (i) and (ii).  $\square$

According to Lemma 3.6 and Lemma 3.7, it remains to compute the invariants  $\langle \text{PD}(A_1), \text{PD}(A_2), \text{PD}(A_3) \rangle_{0,d}$  for the following 3 triples of  $(A_1, A_2, A_3) \in (\mathfrak{B}_8)^3$ :

$$\begin{aligned} A_1 &= A_2 = \mathfrak{a}_{-3}(X)|0, \\ A_3 &= \mathfrak{a}_{-2}(X)\mathfrak{a}_{-1}(\ell)|0, \mathfrak{a}_{-1}(X)\mathfrak{a}_{-2}(\ell)|0, \mathfrak{a}_{-3}(X)|0. \end{aligned}$$

In the next two lemmas, we shall calculate them in terms of (3.12). Put

$$\mathcal{E}_i = \pi_1(\pi_2^* \mathcal{O}_X(i)|_{\mathcal{O}_{Z_3}}) \tag{3.13}$$

where  $\pi_1$  and  $\pi_2$  denote the projections of  $X^{[3]} \times X$  to the two factors. It is known that  $c_1(\mathcal{E}_i) = iD_\ell - B_3/2$ . Using the commutation relations among standard operators on  $\mathbb{H}$  (e.g. the Theorem 3.1 in [LQW4]), we obtain

$$\begin{aligned} c_1(\mathcal{E}_0)^2 &= \mathfrak{a}_{-3}(X)|0 - \mathfrak{a}_{-1}(X)^2\mathfrak{a}_{-1}(x)|0 \\ &\quad - \frac{1}{2}\mathfrak{a}_{-1}(X)\mathfrak{a}_{-1}(\ell)^2|0 - \frac{1}{2}\mathfrak{a}_{-1}(X)\mathfrak{a}_{-2}(K_X)|0. \end{aligned} \tag{3.14}$$

LEMMA 3.8. *Let  $d \geq 1$  and  $A = \mathfrak{a}_{-3}(X)|0$ . Let  $w_1, w_2$  denote the two invariants  $\langle \text{PD}(A), \text{PD}(A), \text{PD}(A_3) \rangle_{0,d}$  for  $A_3 = \mathfrak{a}_{-2}(X)\mathfrak{a}_{-1}(\ell)|0, \mathfrak{a}_{-1}(X)\mathfrak{a}_{-2}(\ell)|0$  respectively. Then,  $w_1 = w_2 = -2d \langle \text{PD}(\mathfrak{a}_{-3}(\ell)|0), \text{PD}(\mathfrak{a}_{-3}(X)|0) \rangle_{0,d}$ .*

*Proof.* Since the arguments for  $w_1$  and  $w_2$  are almost the same, we only prove that  $w_2 = -2d \langle \text{PD}(\mathfrak{a}_{-3}(\ell)|0), \text{PD}(\mathfrak{a}_{-3}(X)|0) \rangle_{0,d}$ . Let  $c_1 = c_1(\mathcal{E}_0) = -B_3/2$  (we regard a divisor as either a homology class or a cohomology class depending on the context). Apply the composition law (2.6) to  $\alpha_1 = \alpha_2 = c_1, \alpha_3 = \text{PD}(\mathfrak{a}_{-3}(X)|0), \alpha_4 = \text{PD}(\mathfrak{a}_{-1}(X)\mathfrak{a}_{-2}(\ell)|0)$ , and to the basis  $\{\Delta_a\}$  of  $H^*(X^{[3]})$  given by (2.12).

First of all, the left-hand-side of (2.6) is equal to

$$\begin{aligned} &\langle c_1^2, \alpha_3, \alpha_4 \rangle_{0,d} + \langle c_1, c_1, \alpha_3\alpha_4 \rangle_{0,d} \\ &+ \sum_{d_1+d_2=d, d_1, d_2 > 0} \sum_a \langle c_1, c_1, \Delta_a \rangle_{0,d_1} \langle \Delta^a, \alpha_3, \alpha_4 \rangle_{0,d_2}. \end{aligned} \tag{3.15}$$

By (3.14) and Lemma 3.6,  $\langle c_1^2, \alpha_3, \alpha_4 \rangle_{0,d} = w_2$ . Since the intersection number  $\langle c_1 \cdot \beta_3 \rangle$  is equal to 1,  $\langle c_1, c_1, \alpha_3\alpha_4 \rangle_{0,d} = d^2 \langle \alpha_3\alpha_4 \rangle_{0,d}$  and  $\langle c_1, c_1, \Delta_a \rangle_{0,d_1} = d_1^2 \langle \Delta_a \rangle_{0,d_1}$ . By Lemma 2.5,  $\langle \Delta_a \rangle_{0,d_1} \neq 0$  only when  $\Delta_a = \text{PD}(\mathfrak{a}_{-2}(\ell)\mathfrak{a}_{-1}(x)|0)$ . Note that  $\Delta^a = -1/2 \text{PD}(\mathfrak{a}_{-1}(X)\mathfrak{a}_{-2}(\ell)|0)$ . So  $\langle \Delta^a, \alpha_3, \alpha_4 \rangle_{0,d_2} = 0$  by Lemma 3.6. It follows from (3.15) that the left-hand-side of (2.6) is equal to

$$w_2 + d^2 \langle \alpha_3\alpha_4 \rangle_{0,d}. \tag{3.16}$$

We claim that  $\langle \alpha_3\alpha_4 \rangle_{0,d} = -12(K_X \cdot \ell)/d^2$ . To prove this, note from (3.14) that  $\mathfrak{a}_{-3}(X)|0 = c_1^2 + \mathfrak{a}_{-1}(X)^2\mathfrak{a}_{-1}(x)|0 + 1/2 \mathfrak{a}_{-1}(X)\mathfrak{a}_{-1}(\ell)^2|0 - 3/2 \mathfrak{a}_{-1}(X)\mathfrak{a}_{-2}(\ell)|0$ . Choose lines  $\ell', \ell''$  in  $X = \mathbb{P}^2$  such that  $\ell, \ell', \ell''$  are in general position. Then,  $(\mathfrak{a}_{-1}(X)\mathfrak{a}_{-2}(\ell)|0) \cap (\mathfrak{a}_{-1}(X)\mathfrak{a}_{-2}(\ell')|0) \cap (\mathfrak{a}_{-1}(X)\mathfrak{a}_{-2}(\ell'')|0) = \emptyset$ . It follows that  $(\mathfrak{a}_{-1}(X)\mathfrak{a}_{-2}(\ell)|0)^3 = 0$ . In view of the linear basis in Lemma 2.3 (ii), we see that

$(\mathbf{a}_{-1}(X)\mathbf{a}_{-2}(\ell)|0\rangle)^2$  is a linear combination of  $\mathbf{a}_{-1}(X)\mathbf{a}_{-1}(x)^2|0\rangle$ ,  $\mathbf{a}_{-1}(\ell)^2\mathbf{a}_{-1}(x)|0\rangle$ ,  $\mathbf{a}_{-1}(\ell)\mathbf{a}_{-2}(x)|0\rangle$ , and  $\mathbf{a}_{-3}(x)|0\rangle$ . Hence  $\langle \text{PD}(\mathbf{a}_{-1}(X)\mathbf{a}_{-2}(\ell)|0\rangle) \alpha_4 \rangle_{0,d} = 0$  according to Lemma 2.5 (i), and we see that  $\langle \alpha_3\alpha_4 \rangle_{0,d}$  is equal to

$$\langle c_1^2\alpha_4 \rangle_{0,d} + \langle \text{PD}(\mathbf{a}_{-1}(X)^2\mathbf{a}_{-1}(x)|0\rangle) \alpha_4 \rangle_{0,d} + \frac{1}{2}\langle \text{PD}(\mathbf{a}_{-1}(X)\mathbf{a}_{-1}(\ell)^2|0\rangle) \alpha_4 \rangle_{0,d}.$$

Since  $(D_\ell)^2 = \mathbf{a}_{-1}(X)\mathbf{a}_{-1}(\ell)^2|0\rangle + 1/2 \mathbf{a}_{-1}(X)^2\mathbf{a}_{-1}(x)|0\rangle$ , we obtain

$$\langle \alpha_3\alpha_4 \rangle_{0,d} = \langle c_1^2\alpha_4 \rangle_{0,d} + \frac{1}{2}\langle D_\ell^2\alpha_4 \rangle_{0,d} + \frac{3}{4}\langle \text{PD}(\mathbf{a}_{-1}(X)^2\mathbf{a}_{-1}(x)|0\rangle) \alpha_4 \rangle_{0,d}. \tag{3.17}$$

Since  $\mathbf{a}_{-1}(X)^2\mathbf{a}_{-1}(x)|0\rangle \cdot \mathbf{a}_{-1}(X)\mathbf{a}_{-2}(\ell)|0\rangle = 2\mathbf{a}_{-2}(\ell)\mathbf{a}_{-1}(x)|0\rangle$ , the third term in (3.17) is equal to  $3(K_X \cdot \ell)/d^2$  by Lemma 2.5 (ii). Since  $D_\ell^2 \cdot \mathbf{a}_{-1}(X)\mathbf{a}_{-2}(\ell)|0\rangle = \mathbf{a}_{-2}(\ell)\mathbf{a}_{-1}(x)|0\rangle + 4\mathbf{a}_{-1}(\ell)\mathbf{a}_{-2}(x)|0\rangle$ , the second term in (3.17) is equal to  $(K_X \cdot \ell)/d^2$  by Lemma 2.5. Using a similar argument, we see that the first term in (3.17) is equal to  $-16(K_X \cdot \ell)/d^2$ . Thus,  $\langle \alpha_3\alpha_4 \rangle_{0,d} = -12(K_X \cdot \ell)/d^2$  in view of (3.17).

Combining with (3.16), we see that the left-hand-side of (2.6) is equal to  $w_2 - 12(K_X \cdot \ell)$ . Similarly, the right-hand-side of (2.6) is equal to

$$-2d \langle \text{PD}(\mathbf{a}_{-3}(\ell)|0\rangle), \text{PD}(\mathbf{a}_{-3}(X)|0\rangle) \rangle_{0,d} - 12(K_X \cdot \ell).$$

Hence we have  $w_2 = -2d \langle \text{PD}(\mathbf{a}_{-3}(\ell)|0\rangle), \text{PD}(\mathbf{a}_{-3}(X)|0\rangle) \rangle_{0,d}$ .  $\square$

LEMMA 3.9. *Let  $d \geq 1$ . Put  $f(d) = d \langle \text{PD}(\mathbf{a}_{-3}(\ell)|0\rangle), \text{PD}(\mathbf{a}_{-3}(X)|0\rangle) \rangle_{0,d}$ . Let  $w_3$  denote  $\langle \text{PD}(A), \text{PD}(A), \text{PD}(A) \rangle_{0,d}$  for  $A = \mathbf{a}_{-3}(X)|0\rangle$ . Then  $w_3$  equals*

$$\begin{aligned} & -24K_X^2 - 18(K_X \cdot \ell) + 5(K_X \cdot \ell)f(d) \\ & -2(K_X \cdot \ell) \sum_{0 < d_1 < d} f(d_1) + \frac{1}{3} \sum_{0 < d_1 < d} f(d_1)f(d - d_1). \end{aligned}$$

*Proof.* Our idea is the same as in the proof of Lemma 3.8. Let  $c_1 = c_1(\mathcal{E}_0)$ . Apply (2.6) to  $\alpha_1 = \alpha_2 = c_1$  and  $\alpha_3 = \alpha_4 = \text{PD}(\mathbf{a}_{-3}(X)|0\rangle)$ . Then, the left-hand-side of (2.6) is still of the form (3.15). By (3.14), Lemma 3.6 and Lemma 3.8,  $\langle c_1^2, \alpha_3, \alpha_4 \rangle_{0,d} = w_3 - (K_X \cdot \ell)/2 w_2 = w_3 + (K_X \cdot \ell)f(d)$ . Also,  $\langle c_1, c_1, \alpha_3\alpha_4 \rangle_{0,d} = d^2 \langle \alpha_3\alpha_4 \rangle_{0,d} = 24K_X^2 + 18(K_X \cdot \ell)$ , and  $\sum_a \langle c_1, c_1, \Delta_a \rangle_{0,d_1} \langle \Delta^a, \alpha_3, \alpha_4 \rangle_{0,d_2}$  is equal to

$$\begin{aligned} & -\frac{d_1^2}{2} \langle \text{PD}(\mathbf{a}_{-2}(\ell)\mathbf{a}_{-1}(x)|0\rangle) \rangle_{0,d_1} \langle \text{PD}(\mathbf{a}_{-1}(X)\mathbf{a}_{-2}(\ell)|0\rangle), \alpha_3, \alpha_4 \rangle_{0,d_2} \\ & = -\frac{d_1^2}{2} \cdot \frac{2(K_X \cdot \ell)}{d_1^2} \cdot (-2f(d_2)) = 2(K_X \cdot \ell)f(d_2) \end{aligned}$$

by Lemma 2.5 (ii) and Lemma 3.8. So the left-hand-side of (2.6) is

$$w_3 + (K_X \cdot \ell)f(d) + 24K_X^2 + 18(K_X \cdot \ell) + 2(K_X \cdot \ell) \sum_{0 < d_1 < d} f(d_1). \tag{3.18}$$

Similarly, the right-hand-side of (2.6) is equal to

$$6(K_X \cdot \ell)f(d) + \frac{1}{3} \sum_{0 < d_1 < d} f(d_1)f(d - d_1). \tag{3.19}$$

Now we prove the lemma by comparing (3.18) and (3.19).  $\square$

The results in this subsection are summarized into a theorem.

**THEOREM 3.10.** *Let  $X = \mathbb{P}^2$ , and  $\mathfrak{B}_8$  be defined in Definition 2.4. Let  $\ell \subset X$  be a line. Let  $d \geq 1$ ,  $f(d) = d \langle \text{PD}(\mathfrak{a}_{-3}(\ell)|0), \text{PD}(\mathfrak{a}_{-3}(X)|0) \rangle_{0,d}$ , and  $A_1, A_2, A_3 \in \mathfrak{B}_8$ . Then, the 3-point genus-0 Gromov-Witten invariant  $\langle \text{PD}(A_1), \text{PD}(A_2), \text{PD}(A_3) \rangle_{0,d}$  is zero unless the unordered triple  $(A_1, A_2, A_3)$  is one of the following:*

- (i)  $(\mathfrak{a}_{-2}(X)\mathfrak{a}_{-1}(\ell)|0, \mathfrak{a}_{-2}(X)\mathfrak{a}_{-1}(\ell)|0, \mathfrak{a}_{-1}(X)\mathfrak{a}_{-2}(\ell)|0)$
- (ii)  $(\mathfrak{a}_{-3}(X)|0, \mathfrak{a}_{-3}(X)|0, \mathfrak{a}_{-2}(X)\mathfrak{a}_{-1}(\ell)|0)$
- (iii)  $(\mathfrak{a}_{-3}(X)|0, \mathfrak{a}_{-3}(X)|0, \mathfrak{a}_{-1}(X)\mathfrak{a}_{-2}(\ell)|0)$
- (iv)  $(\mathfrak{a}_{-3}(X)|0, \mathfrak{a}_{-3}(X)|0, \mathfrak{a}_{-3}(X)|0)$ .

Moreover,  $\langle \text{PD}(A_1), \text{PD}(A_2), \text{PD}(A_3) \rangle_{0,d} = -24$  for case (i); for cases (ii) and (iii),  $\langle \text{PD}(A_1), \text{PD}(A_2), \text{PD}(A_3) \rangle_{0,d} = -2f(d)$ ; for case (iv),

$$\begin{aligned} & \langle \text{PD}(A_1), \text{PD}(A_2), \text{PD}(A_3) \rangle_{0,d} \\ &= -162 - 15f(d) + 6 \sum_{0 < d_1 < d} f(d_1) + \frac{1}{3} \sum_{0 < d_1 < d} f(d_1)f(d - d_1). \end{aligned}$$

□

**4. Computation of  $\langle \text{PD}(\mathfrak{a}_{-3}(\ell)|0), \text{PD}(\mathfrak{a}_{-3}(X)|0) \rangle_{0,d}$ .** In this section, we study the remaining 2-point Gromov-Witten invariant

$$\langle \text{PD}(\mathfrak{a}_{-3}(\ell)|0), \text{PD}(\mathfrak{a}_{-3}(X)|0) \rangle_{0,d}$$

in (3.12). Using the standard  $(\mathbb{C}^*)^2$ -action on  $X = \mathbb{P}^2$  and the virtual localization formula in [G-P], we reduce the computation to a summation over stable graphs. This allows us to calculate  $\langle \text{PD}(\mathfrak{a}_{-3}(\ell)|0), \text{PD}(\mathfrak{a}_{-3}(X)|0) \rangle_{0,d}$  for  $d \leq 4$ .

**4.1. The contracted  $(\mathbb{C}^*)^2$ -invariant curves in  $(\mathbb{P}^2)^{[3]}$ .** Let  $T \subset \text{SL}_3(\mathbb{C})$  be the subgroup consisting of diagonal matrices. Then  $T \simeq (\mathbb{C}^*)^2$  acts on  $\mathbb{P}^2$  with fixed points  $P_0 = (1, 0, 0)$ ,  $P_1 = (0, 1, 0)$  and  $P_2 = (0, 0, 1)$ . There is an induced action of  $T$  on the Hilbert scheme  $(\mathbb{P}^2)^{[3]}$  with a finite number of fixed points. The  $T$ -fixed points in  $(\mathbb{P}^2)^{[3]}$  are enumerated as follows. If  $(u_i, v_i)$  are the local coordinates at the fixed point  $P_i$ , then there are three  $T$ -fixed points in  $M_3(P_i) \subset (\mathbb{P}^2)^{[3]}$  corresponding to the partitions (3), (2, 1) and (1, 1, 1) of 3. The corresponding ideals are  $(u_i^3, v_i)$ ,  $(u_i^2, u_i v_i, v_i^2)$  and  $(u_i, v_i^3)$ . Also for each ordered pair of points  $(P_i, P_j)$  with  $i \neq j$ , we have two fixed points  $R_{i,j}^{(1)} = \xi_{i,1} + P_j$  and  $R_{i,j}^{(2)} = \xi_{i,2} + P_j$  in  $(\mathbb{P}^2)^{[3]}$ , where  $\xi_{i,1}, \xi_{i,2} \in M_2(P_i)$  correspond to the ideals  $(u_i, v_i^2), (u_i^2, v_i)$  respectively. Finally,  $P_0 + P_1 + P_2$  is also a  $T$ -fixed point in  $(\mathbb{P}^2)^{[3]}$ .

Next, we start enumerating  $T$ -invariant curves. Observe that a  $T$ -invariant curve is the closure of a 1-dimensional  $T$ -orbit. Thus, a  $T$ -invariant curve is the  $T$ -orbit of a point in a fixed component of a 1-parameter subgroup of  $T$  corresponding to the kernel of the  $T$ -action along the curve. In particular a  $T$ -invariant curve is a smooth rational curve, and must contain exactly two fixed points.

We are only interested in  $T$ -invariant curves that are contracted under the Hilbert-Chow morphism  $(\mathbb{P}^2)^{[3]} \rightarrow (\mathbb{P}^2)^{(3)}$ . Such curves must be entirely contained in  $M_3(P_i)$  for some  $i$ , or in  $M_2(P_i) + P_j$  for some  $i \neq j$ . Since  $M_2(P_i) \simeq \mathbb{P}^1$ , we immediately obtained six  $T$ -invariant curves  $C_{i,j} \stackrel{\text{def}}{=} M_2(P_i) + P_j$ , with  $1 \leq i, j \leq 3$  and  $i \neq j$ , contracted by the Hilbert-Chow morphism  $(\mathbb{P}^2)^{[3]} \rightarrow (\mathbb{P}^2)^{(3)}$ .

We now analyze  $T$ -invariant curves in  $M_3(P_i)$ , by using a tangent space analysis. Suppose that  $(s, t)(u_i, v_i) = (\lambda_i(s, t)u_i, \mu_i(s, t)v_i)$  where  $\lambda_i$  and  $\mu_i$  are independent

characters of  $T$ . Let  $Q_{i,0}, Q_{i,1}, Q_{i,2} \in M_3(P_i)$  be the three  $T$ -fixed points corresponding to the ideals  $(u_i^2, u_i v_i, v_i^2), (u_i^3, v_i), (u_i, v_i^3)$  respectively. For simplicity, denote the tangent space of  $(\mathbb{P}^2)^{[3]}$  at the point  $Q_{i,j}$  by  $T_{Q_{i,j}}$ . By [E-S], we have the following decompositions for the tangent spaces as a representation of  $T$ :

$$T_{Q_{i,0}} = 2\lambda_i^{-1} + 2\mu_i^{-1} + \lambda_i^{-2}\mu_i + \lambda_i\mu_i^{-2} \tag{4.1}$$

$$T_{Q_{i,1}} = \lambda_i^{-1}\mu_i^2 + \lambda_i^{-1}\mu_i + \lambda_i^{-1} + \mu_i^{-3} + \mu_i^{-2} + \mu_i^{-1} \tag{4.2}$$

$$T_{Q_{i,2}} = \lambda_i^{-3} + \lambda_i^{-2} + \lambda_i^{-1} + \lambda_i^2\mu_i^{-1} + \lambda_i\mu_i^{-1} + \mu_i^{-1}. \tag{4.3}$$

The kernel of each character appearing in equations (4.1), (4.2), (4.3) determines 1-parameter subgroup whose fixed locus contains  $T$ -invariant curves. Since we are interested only in  $T$ -invariant curves contained in  $M_3(P_i)$ , we need only to analyze characters of the form  $\lambda_i^k \mu_i^\ell$  with  $k\ell \neq 0$ . (The kernel of a character  $\lambda_i^k$  or  $\mu_i^\ell$  will have fixed locus that moves out of the punctual Hilbert scheme.)

Looking at  $T_{Q_{i,0}}$  we see that the character  $\lambda_i\mu_i^{-2}$  has multiplicity one. This means that its kernel has one-dimensional fixed component containing the point  $Q_{i,0}$ . Now the character  $\lambda_i^{-1}\mu_i^2$  in  $T_{Q_{i,1}}$  has the same kernel as the character  $\lambda_i\mu_i^{-2}$  in  $T_{Q_{i,0}}$ . So there is a unique  $T$ -invariant curve, denoted by  $C_{0,1}^{(i)}$ , which contains  $Q_{i,0}$  and  $Q_{i,1}$ , and is the fixed locus of  $\ker(\lambda_i\mu_i^{-2})$ . Similar analysis shows that there are two other  $T$ -invariant curves  $C_{0,2}^{(i)}$  and  $C_{1,2}^{(i)}$  in  $M_3(P_i)$ ; namely,  $C_{0,2}^{(i)}$  through  $Q_{i,0}$  and  $Q_{i,2}$  which is the fixed locus of  $\ker(\lambda_i^{-2}\mu_i)$ , while  $C_{1,2}^{(i)}$  through  $Q_{i,1}$  and  $Q_{i,2}$  which is the fixed locus of  $\ker(\lambda_i^{-1}\mu_i)$ . This analysis partially proves the following.

LEMMA 4.1. *There are 15  $T$ -invariant curves contracted under the Hilbert-Chow morphism  $(\mathbb{P}^2)^{[3]} \rightarrow (\mathbb{P}^2)^{(3)}$ . They are described as follows:*

- (i) *the six curves  $C_{i,j} = M_2(P_i) + P_j$  where  $1 \leq i, j \leq 3$  and  $i \neq j$ ;*
- (ii) *the nine curves  $C_{k,\ell}^{(i)} \subset M_3(P_i)$  where  $1 \leq i \leq 3$  and  $0 \leq k < \ell \leq 2$ .*

Furthermore,  $C_{1,2}^{(i)} \sim 3\beta_3$  and  $C_{0,1}^{(i)} \sim C_{0,2}^{(i)} \sim \beta_3$  for every  $i$ .

*Proof.* It remains to prove the last sentence. Identify  $M_3(P_i)$  with the punctual Hilbert scheme  $\text{Hilb}^3(\mathbb{C}^2, 0)$ . By (2.15),  $C_{1,2}^{(i)} = \bar{\sigma}_3$ . It follows from Lemma 2.8 that  $C_{1,2}^{(i)} \sim 3\beta_3$ . Similarly, we see from (2.13) and Lemma 2.7 that  $C_{0,1}^{(i)} \sim C_{0,2}^{(i)} \sim \beta_3$ .  $\square$

Next, we compute the equivariant first Chern classes of the restrictions of the tautological bundles (3.13) to the  $T$ -fixed points in  $(\mathbb{P}^2)^{[3]}$ . Let  $w_i = c_1(\lambda_i)$  and  $z_i = c_1(\mu_i)$  in the equivariant Chow group  $A_*^T(pt)$ . If we put  $(w_0, z_0) = (w, z)$ , then  $(w_1, z_1) = (-w, -w + z)$  and  $(w_2, z_2) = (-z, -z + w)$ .

LEMMA 4.2. *Let  $g_0 = 0, g_1 = w,$  and  $g_2 = z$ . There are  $T$ -linearizations on  $\mathcal{E}_0$  and  $\mathcal{E}_1$  such that  $c_1(\mathcal{E}_0|_{R_{i,j}^{(1)}}) = z_i, c_1(\mathcal{E}_0|_{R_{i,j}^{(2)}}) = w_i, c_1(\mathcal{E}_0|_{Q_{i,0}}) = z_i + w_i, c_1(\mathcal{E}_0|_{Q_{i,1}}) = 3z_i, c_1(\mathcal{E}_0|_{Q_{i,2}}) = 3w_i$  and  $c_1(\mathcal{E}_1|_{R_{i,j}^{(1)}}) = 2g_i + g_j + z_i, c_1(\mathcal{E}_1|_{R_{i,j}^{(2)}}) = 2g_i + g_j + w_i, c_1(\mathcal{E}_1|_{Q_{i,0}}) = 3g_i + z_i + w_i, c_1(\mathcal{E}_1|_{Q_{i,1}}) = 3g_i + 3z_i, c_1(\mathcal{E}_1|_{Q_{i,2}}) = 3g_i + 3w_i$ .*

*Proof.* The proofs of these conclusions are similar. For instance, let us prove  $c_1(\mathcal{E}_1|_{R_{i,j}^{(2)}}) = 2g_i + g_j + w_i$ . Note that the fiber  $\mathcal{E}_1|_{R_{i,j}^{(2)}}$  is canonically identified with  $\mathcal{O}_X(1) \otimes \mathcal{O}_X/I_{R_{i,j}^{(2)}}$ . Since  $R_{i,j}^{(2)} = \xi_{i,2} + P_j$ ,  $\mathcal{E}_1|_{R_{i,j}^{(2)}}$  is canonically identified with  $(\mathcal{O}_X(1) \otimes \mathcal{O}_X/I_{\xi_{i,2}}) \oplus (\mathcal{O}_X(1) \otimes \mathcal{O}_X/I_{P_j})$ . Therefore,

$$c_1(\mathcal{E}_1|_{R_{i,j}^{(2)}}) = 2c_1(\mathcal{O}_X(1)|_{P_i}) + c_1(\mathcal{O}_X/I_{\xi_{i,2}}) + c_1(\mathcal{O}_X(1)|_{P_j}).$$

Since  $\mathcal{O}_X(1)|_{P_i} \cong (\mathbb{C} \oplus \mathbb{C})/(\mathbb{C}P_i)$ , we have  $c_1(\mathcal{O}_X(1)|_{P_i}) = g_i$ . Using  $c_1(\mathcal{O}_X/I_{\xi_{i,2}}) = c_1(\lambda_i) = w_i$ , we conclude that  $c_1(\mathcal{E}_1|_{R_{i,j}^{(2)}}) = 2g_i + g_j + w_i$ .  $\square$

**4.2. The Euler characteristic for a covering.** An important step in computing the virtual Euler class of the  $T$ -fixed locus  $\mathfrak{M}_{0,2}((\mathbb{P}^2)^{[3]}, d, \beta_3)^T$  is to compute (as a representation)  $\chi(f^*T_{(\mathbb{P}^2)^{[3]}})$  where  $f : \mathbb{P}^1 \rightarrow (\mathbb{P}^2)^{[3]}$  is a degree- $d$  morphism such that the image is one of the 15  $T$ -invariant curves in Lemma 4.1 and  $f$  is totally ramified at the two  $T$ -fixed points in  $f(\mathbb{P}^1)$ .

**4.2.1. Degree- $d$  coverings of  $C_{k,\ell}^{(i)}$ .** Observe that if  $\mathbb{P}^1 \rightarrow (\mathbb{P}^2)^{[3]}$  is a degree- $d$   $T$ -equivariant morphism with image  $C_{k,\ell}^{(i)}$ , then the characters of  $T$ -action on  $\mathbb{P}^1$  are (using multiplicative notation)  $\alpha^{1/d}, \beta^{1/d}$  where  $\alpha, \beta$  are the characters of the  $T$ -action on the image curve  $C_{k,\ell}^{(i)}$ . Let  $S_{i,k}$  and  $S_{i,\ell}$  be the two fixed points of the action on  $\mathbb{P}^1$  denoted so that the image of  $S_{i,k}$  is  $Q_{i,k}$  and the image of  $S_{i,\ell}$  is  $Q_{i,\ell}$ . If  $V$  is a  $T$ -equivariant vector bundle on  $\mathbb{P}^1$ , then the localization theorem for equivariant  $K$ -theory says that

$$\chi(V) = \frac{V|_{S_{i,k}}}{1 - T_{\mathbb{P}^1}^*|_{S_{i,k}}} + \frac{V|_{S_{i,\ell}}}{1 - T_{\mathbb{P}^1}^*|_{S_{i,\ell}}} \tag{4.4}$$

where  $T_{\mathbb{P}^1}^*$  is the cotangent bundle of  $\mathbb{P}^1$ . Since  $T_{\mathbb{P}^1}^*|_{S_{i,k}} \cong T_{C_{k,\ell}^{(i)}}^*|_{Q_{i,k}}$ , we can use formulas (4.1), (4.2), (4.3) to determine  $\chi(f^*T_{(\mathbb{P}^2)^{[3]}})$ .

First of all, let  $f(\mathbb{P}^1) = C_{0,1}^{(i)}$ . The curve  $C_{0,1}^{(i)}$  is a component of the fixed locus of  $\ker(\lambda_i \mu_i^{-2})$ . Thus, reading off (4.1) and (4.2), we see that  $T_{C_{0,1}^{(i)}}|_{Q_{i,0}} = \lambda_i \mu_i^{-2}$  and  $T_{C_{0,1}^{(i)}}|_{Q_{i,1}} = \lambda_i^{-1} \mu_i^2$ . Thus  $T_{\mathbb{P}^1}|_{S_{i,0}} = \gamma_i \theta_i^{-2}$  and  $T_{\mathbb{P}^1}|_{S_{i,1}} = \gamma_i^{-1} \theta_i^2$  where  $\gamma_i^d = \lambda_i$  and  $\theta_i^d = \mu_i$ . Substituting (4.1) and (4.2) into the localization formula (4.4) yields

$$\begin{aligned} \chi(f^*T_{(\mathbb{P}^2)^{[3]}}) &= \frac{\lambda_i \mu_i^{-2} + \mu_i^{-1} + \lambda_i^{-1} + \lambda_i^{-2} \mu_i + \lambda_i^{-1} + \mu_i^{-1}}{1 - \gamma_i^{-1} \theta_i^2} \\ &+ \frac{\lambda_i^{-1} \mu_i^2 + \lambda_i^{-1} \mu_i + \lambda_i^{-1} + \mu_i^{-3} + \mu_i^{-2} + \mu_i^{-1}}{1 - \gamma_i \theta_i^{-2}}. \end{aligned}$$

Since  $1/(1 - \gamma_i^{-1} \theta_i^2) = -\gamma_i \theta_i^{-2}/(1 - \gamma_i \theta_i^{-2})$ , the right hand side can be rewritten as

$$\begin{aligned} &\frac{1}{1 - \gamma_i \theta_i^{-2}} [(\lambda_i^{-1} \mu_i^2 + \lambda_i^{-1} \mu_i + \lambda_i^{-1} + \mu_i^{-3} + \mu_i^{-2} + \mu_i^{-1}) - \gamma_i \theta_i^{-2} ((\lambda_i^2 \mu_i^{-4})(\lambda_i^{-1} \mu_i^2) \\ &+ (\lambda_i \mu_i^{-2}) \lambda_i^{-1} \mu_i + \lambda_i^{-1} + (\lambda_i^{-2} \mu_i^4) \mu_i^{-3} + (\lambda_i^{-1} \mu_i^2) \mu_i^{-2} + \mu_i^{-1})]. \end{aligned}$$

Using  $\lambda_i = \gamma_i^d$  and  $\mu_i = \theta_i^d$ , we conclude that  $\chi(f^*T_{(\mathbb{P}^2)^{[3]}})$  is equal to

$$\begin{aligned} &\lambda_i^{-1} \mu_i^2 \sum_{m=0}^{2d} (\gamma_i \theta_i^{-2})^m + \lambda_i^{-1} \mu_i \sum_{m=0}^d (\gamma_i \theta_i^{-2})^m + \lambda_i^{-1} \\ &- \mu_i^{-3} (\gamma_i \theta_i^{-2})^{-2d+1} \sum_{m=0}^{2d-2} (\gamma_i \theta_i^{-2})^m - \mu_i^{-2} (\gamma_i \theta_i^{-2})^{-d+1} \sum_{m=0}^{d-2} (\gamma_i \theta_i^{-2})^m + \mu_i^{-1}. \end{aligned}$$

To simplify this further, set  $\Theta_{0,1}^{(i)} = \sum_{m=1}^{d-1} (\gamma_i \theta_i^{-2})^m = \sum_{m=1}^{d-1} (\lambda_i \mu_i^{-2})^{m/d}$  (with the

understanding that  $\Theta_{0,1}^{(i)} = 0$  when  $d = 1$ ). Then we see that  $\chi(f^*T_{(\mathbb{P}^2)^{[3]}})$  equals

$$(1 + \lambda_i^{-1}\mu_i^2 + \lambda_i\mu_i^{-2} + \lambda_i^{-1}\mu_i + \mu_i^{-1} + \lambda_i^{-1} + \mu_i^{-1} - \lambda_i^{-1}\mu_i^{-1}) + (\lambda_i^{-1}\mu_i^2 + 1 + \lambda_i^{-1}\mu_i - \lambda_i^{-2}\mu_i - \lambda_i^{-1}\mu_i^{-1} - \lambda_i^{-1})\Theta_{0,1}^{(i)}. \tag{4.5}$$

By symmetry, if  $f(\mathbb{P}^1) = C_{0,2}^{(i)}$ , then  $\chi(f^*T_{(\mathbb{P}^2)^{[3]}})$  is equal to

$$(1 + \mu_i^{-1}\lambda_i^2 + \mu_i\lambda_i^{-2} + \mu_i^{-1}\lambda_i + \lambda_i^{-1} + \mu_i^{-1} + \lambda_i^{-1} - \mu_i^{-1}\lambda_i^{-1}) + (\mu_i^{-1}\lambda_i^2 + 1 + \mu_i^{-1}\lambda_i - \mu_i^{-2}\lambda_i - \mu_i^{-1}\lambda_i^{-1} - \mu_i^{-1})\Theta_{0,2}^{(i)} \tag{4.6}$$

where  $\Theta_{0,2}^{(i)} = \sum_{m=1}^{d-1} (\mu_i\lambda_i^{-2})^{m/d}$ , and as above  $\Theta_{0,2}^{(i)} = 0$  if  $d = 1$ .

Next, let  $f(\mathbb{P}^1) = C_{1,2}^{(i)}$ . Then  $T_{C_{1,2}^{(i)}}|_{Q_{i,1}} = \lambda_i^{-1}\mu_i$  and  $T_{C_{1,2}^{(i)}}|_{Q_{i,2}} = \lambda_i\mu_i^{-1}$ . Thus  $T_{\mathbb{P}^1}|_{S_{i,1}} = \gamma_i^{-1}\theta_i$  and  $T_{\mathbb{P}^1}|_{S_{i,2}} = \gamma_i\theta_i^{-1}$ . By (4.4), (4.2) and (4.3),  $\chi(f^*T_{(\mathbb{P}^2)^{[3]}})$  equals

$$\frac{1}{1 - \gamma_i\theta_i^{-1}} [(\lambda_i^{-1}\mu_i^2 + \lambda_i^{-1}\mu_i + \lambda_i^{-1} + \mu_i^{-3} + \mu_i^{-2} + \mu_i^{-1}) - \gamma_i\theta_i^{-1}(\lambda_i^2\mu_i^{-1} + \lambda_i\mu_i^{-1} + \mu_i^{-1} + \lambda_i^{-3} + \lambda_i^{-2} + \lambda_i^{-1})]$$

As above, the numerator is divisible by  $(1 - \gamma_i\theta_i^{-1})$ , and  $\chi(f^*T_{(\mathbb{P}^2)^{[3]}})$  is equal to

$$\lambda_i^{-1} \sum_{s=0}^2 \mu_i^s \sum_{m=0}^{(s+1)d} (\gamma_i\theta_i^{-1})^m - \sum_{s=1}^3 \lambda_i^{-s} \sum_{m=1}^{sd-1} (\gamma_i\theta_i^{-1})^m.$$

Let  $\Theta_{1,2}^{(i)} = \sum_{m=1}^{d-1} (\lambda_i\mu_i^{-1})^{m/d}$  with  $\Theta_{1,2}^{(i)} = 0$  when  $d = 1$ . Then  $\chi(f^*T_{(\mathbb{P}^2)^{[3]}})$  equals

$$\lambda_i^{-1}(1 + \Theta_{1,2}^{(i)}) + \mu_i^{-1} + \lambda_i^{-1}\mu_i(1 + \theta_{1,2}^{(i)}) + (1 + \theta_{1,2}^{(i)}) + \lambda_i\mu_i^{-1} + \lambda_i^{-1}\mu_i^2(1 + \Theta_{1,2}^{(i)}) + \mu_i(1 + \Theta_{1,2}^{(i)}) + \lambda_i(1 + \Theta_{1,2}^{(i)}) + \lambda_i^2\mu_i^{-1} - \lambda_i^{-1}\Theta_{1,2}^{(i)} - (\lambda_i^{-2}\Theta_{1,2}^{(i)} + \lambda_i^{-1}\mu_i^{-1}(1 + \Theta_{1,2}^{(i)})) - (\lambda_i^{-3}\Theta_{1,2}^{(i)} + \lambda_i^{-2}\mu_i^{-1}(1 + \Theta_{1,2}^{(i)}) + \lambda_i^{-1}\mu_i^{-2}(1 + \Theta_{1,2}^{(i)})).$$

Rearranging the terms, we conclude that  $\chi(f^*T_{(\mathbb{P}^2)^{[3]}})$  is equal to

$$(\lambda_i^{-1} + \mu_i^{-1} + \lambda_i^{-1}\mu_i + 1 + \lambda_i\mu_i^{-1} + \lambda_i^{-1}\mu_i^2 + \mu_i + \lambda_i + \lambda_i^2\mu_i^{-1} - \lambda_i^{-1}\mu_i^{-1} - \lambda_i^{-2}\mu_i^{-1} - \lambda_i^{-1}\mu_i^{-2}) + (1 + \lambda_i^{-1}\mu_i^2 + \mu_i + \lambda_i + \lambda_i^{-1}\mu_i - \lambda_i^{-2} - \lambda_i^{-1}\mu_i^{-1} - \lambda_i^{-3} - \lambda_i^{-2}\mu_i^{-1} - \lambda_i^{-1}\mu_i^{-2})\Theta_{1,2}^{(i)}. \tag{4.7}$$

**4.2.2. Degree- $d$  coverings of  $C_{i,j}$ .** Consider maps  $f : \mathbb{P}^1 \rightarrow (\mathbb{P}^2)^{[3]}$  which are degree- $d$  and have image  $C_{i,j}$ . To compute  $\chi(f^*T_{(\mathbb{P}^2)^{[3]}})$ , we recall from subsection 4.1 that the  $T$ -fixed points on  $C_{i,j}$  are  $R_{i,j}^{(1)}$  and  $R_{i,j}^{(2)}$ . Using the results in [E-S], we have the following decompositions for the tangent spaces of  $(\mathbb{P}^2)^{[3]}$  at  $R_{i,j}^{(1)}$  and  $R_{i,j}^{(2)}$  as representations of  $T$ :

$$T_{R_{i,j}^{(1)}} = \lambda_i^{-1}\mu_i + \lambda_i^{-1} + \mu_i^{-2} + \mu_i^{-1} + \lambda_j^{-1} + \mu_j^{-1}, \tag{4.8}$$

$$T_{R_{i,j}^{(2)}} = \lambda_i^{-2} + \lambda_i^{-1} + \lambda_i\mu_i^{-1} + \mu_i^{-1} + \lambda_j^{-1} + \mu_j^{-1}. \tag{4.9}$$

Also,  $T_{C_{i,j}}|_{R_{i,j}^{(1)}} = \lambda_i^{-1}\mu_i$  and  $T_{C_{i,j}}|_{R_{i,j}^{(2)}} = \lambda_i\mu_i^{-1}$ . By (4.4),  $\chi(f^*T_{(\mathbb{P}^2)^{[3]}})$  equals

$$\frac{\lambda_i^{-1}\mu_i + \lambda_i^{-1} + \mu_i^{-2} + \mu_i^{-1} + \lambda_j^{-1} + \mu_j^{-1}}{1 - \gamma_i\theta_i^{-1}} + \frac{\lambda_i^{-2} + \lambda_i^{-1} + \lambda_i\mu_i^{-1} + \mu_i^{-1} + \lambda_j^{-1} + \mu_j^{-1}}{1 - \gamma_i^{-1}\theta_i}$$

So we obtain the following formula for  $\chi(f^*T_{(\mathbb{P}^2)^{[3]}})$ :

$$(1 + \lambda_i^{-1}\mu_i + \lambda_i\mu_i^{-1} + \lambda_i^{-1} + \mu_i^{-1} + \lambda_j^{-1} + \mu_j^{-1} - \lambda_i^{-1}\mu_i^{-1}) + (1 + \lambda_i^{-1}\mu_i - \lambda_i^{-2} - \lambda_i^{-1}\mu_i^{-1})\Theta_{1,2}^{(i)} \tag{4.10}$$

**4.3.  $T$ -invariant stable maps, stable graphs and localizations.** Let  $X = \mathbb{P}^2$ . Note that if  $[f : (C; p_1, p_2) \rightarrow X^{[3]}] \in \overline{\mathfrak{M}}_{0,2}(X^{[3]}, d\beta_3)$  is  $T$ -invariant and if  $\mathbb{P}^1$  is an irreducible component of  $C$  with nonconstant  $f|_{\mathbb{P}^1}$ , then  $f(\mathbb{P}^1)$  is one of the 15  $T$ -invariant curves in Lemma 4.1. The restriction  $f|_{\mathbb{P}^1}$  is ramified at exactly two points with ramification index  $\deg(f|_{\mathbb{P}^1})$ . Since  $f|_{\mathbb{P}^1}$  is ramified at every special point,  $\mathbb{P}^1$  contains at most two special points. Moreover,  $f$  maps the contracted components and the special points (i.e., marked points, nodal points and ramification points) of  $C$  into the  $T$ -fixed point set  $(X^{[3]})^T$ .

Following the book [C-K], to each  $T$ -invariant stable map  $[f : (C; p_1, p_2) \rightarrow X^{[3]}] \in \overline{\mathfrak{M}}_{0,2}(X^{[3]}, d\beta_3)$ , we can associate a marked graph  $\Gamma$  called a *stable graph of genus-0*. The graph  $\Gamma$  has one vertex for each connected component of  $f^{-1}((X^{[3]})^T)$ . It has one edge  $e$  for each non-contracted component  $C_e \simeq \mathbb{P}^1$ , whose two vertices correspond to the connected components of  $f^{-1}((X^{[3]})^T)$  containing the two ramification points in the component  $C_e$ . The edge  $e$  is marked with the degree  $d_e \stackrel{\text{def}}{=} \deg(f|_{C_e})$ . Note that the morphism  $f$  defines a labeling map  $\mathfrak{L}$  from the vertices of  $\Gamma$  to  $(X^{[3]})^T$ . Finally, a vertex is marked with  $\{1\}$  (respectively,  $\{2\}$ , or  $\{1, 2\}$ ) if the connected component of  $f^{-1}((X^{[3]})^T)$  corresponding to the vertex contains the marked point  $p_1$  (respectively,  $p_2$ , or both  $p_1$  and  $p_2$ ).

To a stable graph  $\Gamma$ , we introduce the following notation (cf. [C-K]). Recall that a flag  $F$  is a pair  $(v, e)$  consisting of an edge  $e$  and a vertex  $v$  of  $e$ . For a flag  $F = (v, e)$ , define  $i(F) = \mathfrak{L}(v)$ . Let  $S(v)$  be the number of markings of  $v$ , and  $val(v)$  be the valance of  $v$  (i.e., the number of edges  $e$  such that  $v$  is a vertex of  $e$ ). Let  $n(F) = n(v) = val(v) + S(v)$ . If  $val(v) = 1$ , let  $F(v)$  be the single flag containing  $v$ ; if  $val(v) = 2$ , let  $F_1(v)$  and  $F_2(v)$  denote the two flags containing  $v$ .

Now the connected components of  $\overline{\mathfrak{M}}_{0,2}(X^{[3]}, d\beta_3)^T$  are enumerated by stable graphs corresponding to stable maps whose images are unions of the 15  $T$ -invariant curves in Lemma 4.1 and whose contracted components and special points are mapped into  $(X^{[3]})^T$ . We use  $\Gamma$  to denote these stable graphs, and use  $\mathfrak{M}_\Gamma$  to denote the corresponding connected components of  $\overline{\mathfrak{M}}_{0,2}(X^{[3]}, d\beta_3)^T$ . If  $\Gamma$  is a stable graph, let  $M_\Gamma = \prod_{n(v) \geq 3} \overline{M}_{0,n(v)}$  where  $\overline{M}_{0,n(v)}$  is the (fine) moduli space of  $n(v)$ -pointed stable rational curves. As discussed in [C-K], there is a finite map  $M_\Gamma \rightarrow \mathfrak{M}_\Gamma$  such that  $\mathfrak{M}_\Gamma = M_\Gamma/\mathbf{A}_\Gamma$  where  $\mathbf{A}_\Gamma$  fits in the exact sequence

$$0 \rightarrow \prod_e \mathbb{Z}/d_e\mathbb{Z} \rightarrow \mathbf{A}_\Gamma \rightarrow \text{Aut}(\Gamma) \rightarrow 0.$$

Since a stable curve is connected, we see from the description of the  $T$ -invariant curves in Lemma 4.1 that a summation over all the stable graphs  $\Gamma$  breaks up as

$$\sum_{\Gamma} = \sum_{1 \leq i \neq j \leq 3} \sum_{\Gamma \in \mathcal{S}_{d,i,j}} + \sum_{i=1}^3 \sum_{\Gamma \in \mathcal{T}_{d,i}} \tag{4.11}$$

where  $\mathcal{S}_{d,i,j}$  is the set of all stable graphs  $\Gamma$  such that  $f(C) = C_{i,j}$  for every  $[f : (C; p_1, p_2) \rightarrow X^{[3]}] \in \mathfrak{M}_\Gamma$ , and  $\mathcal{T}_{d,i}$  is the set of all stable graphs  $\Gamma$  such that  $f(C) \subset C_{0,1}^{(i)} \cup C_{0,2}^{(i)} \cup C_{1,2}^{(i)}$  for every  $[f : (C; p_1, p_2) \rightarrow X^{[3]}] \in \mathfrak{M}_\Gamma$ .

Our goal of this section is to study  $\langle \text{PD}(\mathbf{a}_{-3}(\ell)|0), \text{PD}(\mathbf{a}_{-3}(X)|0) \rangle_{0,d}$ . To apply the localization formula more effectively, we rewrite this 2-point invariant by using the Chern classes of tautological bundles over  $X^{[3]} = (\mathbb{P}^2)^{[3]}$  defined in (3.13). Let

$$A = (c_1(\mathcal{E}_1) - c_1(\mathcal{E}_0))c_1(\mathcal{E}_0)^2 \quad \text{and} \quad B = c_1(\mathcal{E}_0)^2.$$

Intersecting (3.14) with  $D_\ell = c_1(\mathcal{E}_1) - c_1(\mathcal{E}_0)$ , we see that  $A$  is equal to

$$\begin{aligned} & 3\mathbf{a}_{-3}(\ell)|0 - 3\mathbf{a}_{-1}(X)\mathbf{a}_{-1}(\ell)\mathbf{a}_{-1}(x)|0 \\ & - \frac{1}{2}\mathbf{a}_{-1}(\ell)^3|0 + 3\mathbf{a}_{-1}(X)\mathbf{a}_{-2}(x)|0 + \frac{3}{2}\mathbf{a}_{-2}(\ell)\mathbf{a}_{-1}(\ell)|0. \end{aligned}$$

By Lemma 3.1, Lemma 3.2 and Lemma 3.4 (i), we obtain

$$\langle A, B \rangle_{0,d} = 3 \langle \text{PD}(\mathbf{a}_{-3}(\ell)|0), \text{PD}(\mathbf{a}_{-3}(X)|0) \rangle_{0,d} \tag{4.12}$$

where for notational simplicity, we make no distinction between the algebraic cycles  $A, B$  and their corresponding cohomology classes.

By the virtual localization formula of [G-P], we have

$$\langle A, B \rangle_{0,d} = \int_{[\mathfrak{M}_{0,2}(X^{[3]}, d\beta_3)]^{\text{vir}}} ev_2^*(A \otimes B) = \sum_{\Gamma} \frac{1}{|\mathbf{A}_\Gamma|} \int_{[M_\Gamma]^{\text{vir}}} \frac{(A \otimes B)_\Gamma}{e(N_\Gamma^{\text{vir}})}. \tag{4.13}$$

Here  $[M_\Gamma]^{\text{vir}}$  is the pullback of  $[\mathfrak{M}_\Gamma]^{\text{vir}}$  to  $M_\Gamma$  via the finite map  $M_\Gamma \rightarrow \mathfrak{M}_\Gamma$ . Likewise,  $(A \otimes B)_\Gamma$  is the pullback of  $ev_2^*(A \otimes B)|_{\mathfrak{M}_\Gamma}$  to  $M_\Gamma$ , and  $e(N_\Gamma^{\text{vir}})$  is the pullback of the Euler class of the moving part  $N_\Gamma^{\text{vir}}$  of the tangent-obstruction complex.

Let  $\Gamma$  be a stable graph such that the labeling  $\mathcal{L}$  maps the marked vertices of  $\Gamma$  to the same point in  $(X^{[3]})^T$ . Then we have  $(A \otimes B)_\Gamma = (1_X \otimes AB)_\Gamma$  where  $1_X \in H^0(X)$  is the fundamental cohomology class. By the fundamental class axiom,  $\langle 1_X, AB \rangle_{0,d} = 0$ . Thus in view of (4.13) and (4.11), we obtain

$$\begin{aligned} \langle A, B \rangle_{0,d} &= \langle A, B \rangle_{0,d} - \langle 1_X, AB \rangle_{0,d} \\ &= \sum_{\Gamma} \int_{[M_\Gamma]^{\text{vir}}} \frac{(A \otimes B)_\Gamma - (1_X \otimes AB)_\Gamma}{|\mathbf{A}_\Gamma| e(N_\Gamma^{\text{vir}})} = \sum_{1 \leq i \neq j \leq 3} \sum_{\Gamma \in \mathcal{S}'_{d,i,j}} + \sum_{i=1}^3 \sum_{\Gamma \in \mathcal{T}'_{d,i}} \end{aligned} \tag{4.14}$$

where the three prime signs indicate that we only sum over stable graphs  $\Gamma$  such that the two marked vertices of  $\Gamma$  have distinct labels in  $(X^{[3]})^T$ . In other words, putting  $\mathcal{S}'_{d,i,j} = \sum_{\Gamma \in \mathcal{S}'_{d,i,j}}$  and  $\mathcal{T}'_{d,i} = \sum_{\Gamma \in \mathcal{T}'_{d,i}}$ , we have

$$\langle A, B \rangle_{0,d} = \sum_{1 \leq i \neq j \leq 3} \mathcal{S}'_{d,i,j} + \sum_{i=1}^3 \mathcal{T}'_{d,i}. \tag{4.15}$$

**4.4. Computation of  $\mathcal{S}'_{d,i,j}$ .** Let  $\mathcal{S}''_{d,i,j} = \mathcal{S}'_{d,i,j} / \sim$  where  $\Gamma_1 \sim \Gamma_2$  if  $\Gamma_1$  and  $\Gamma_2$  are identical except that the vertex which is marked with  $\{1\}$  (respectively, with  $\{2\}$ ) in  $\Gamma_1$  is marked with  $\{2\}$  (respectively, with  $\{1\}$ ) in  $\Gamma_2$ . Then each graph  $\Gamma$  in  $\mathcal{S}''_{d,i,j}$  gives rise to two graphs  $\Gamma_1, \Gamma_2$  in  $\mathcal{S}'_{d,i,j}$ . However, there is no ambiguity to define

$$e_{d,i,j} = \sum_{\Gamma \in \mathcal{S}''_{d,i,j}} \int_{[M_{\Gamma_1}]^{\text{vir}}} \frac{1}{|\mathbf{A}_{\Gamma_1}| e(N_{\Gamma_1}^{\text{vir}})}. \tag{4.16}$$

By the definition of  $\mathcal{S}_{d,i,j}$ ,  $f(C) = C_{i,j}$  for every stable map  $[f : (C; p_1, p_2) \rightarrow X^{[3]}]$  in  $\mathfrak{M}_{\Gamma_1}$  or  $\mathfrak{M}_{\Gamma_2}$ . Recall that  $R_{i,j}^{(1)}$  and  $R_{i,j}^{(2)}$  are the two  $T$ -fixed points in  $C_{i,j}$ . So

$$\begin{aligned} & \int_{[M_{\Gamma_1}]^{\text{vir}}} \frac{(A \otimes B)_{\Gamma_1} - (1_X \otimes AB)_{\Gamma_1}}{|\mathbf{A}_{\Gamma_1}| e(N_{\Gamma_1}^{\text{vir}})} + \int_{[M_{\Gamma_2}]^{\text{vir}}} \frac{(A \otimes B)_{\Gamma_2} - (1_X \otimes AB)_{\Gamma_2}}{|\mathbf{A}_{\Gamma_2}| e(N_{\Gamma_2}^{\text{vir}})} \\ &= -(A|_{R_{i,j}^{(1)}} - A|_{R_{i,j}^{(2)}})(B|_{R_{i,j}^{(1)}} - B|_{R_{i,j}^{(2)}}) \cdot \int_{[M_{\Gamma_1}]^{\text{vir}}} \frac{1}{|\mathbf{A}_{\Gamma_1}| e(N_{\Gamma_1}^{\text{vir}})}. \end{aligned}$$

Combining this with Lemma 4.2 and (4.16), we conclude that

$$S'_{d,i,j} = -(2g_i + g_j)(w_i^2 - z_i^2)^2 e_{d,i,j}. \tag{4.17}$$

To compute  $e_{d,i,j}$ , we calculate the contribution from a graph  $\Gamma_1$  by considering the restriction of the tangent-obstruction complex on  $\overline{\mathfrak{M}}_{0,2}(X^{[3]}, d\beta_3)$  to  $\mathfrak{M}_{\Gamma_1}$ . Following [G-P], the fibers of its cohomology sheaves,  $\mathcal{T}^1$  and  $\mathcal{T}^2$ , at a point associated to a stable map  $[f : (C; p_1, p_2) \rightarrow X^{[3]}]$  fit into the exact sequence

$$\begin{aligned} 0 &\rightarrow \text{Ext}^0(\Omega_C(p_1 + p_2), \mathcal{O}_C) \rightarrow H^0(C, f^*T_{X^{[3]}}) \rightarrow \mathcal{T}^1 \\ &\rightarrow \text{Ext}^1(\Omega_C(p_1 + p_2), \mathcal{O}_C) \rightarrow H^1(C, f^*T_{X^{[3]}}) \rightarrow \mathcal{T}^2 \rightarrow 0. \end{aligned}$$

To obtain the contribution of the moving parts of each term in the sequence, we use an analysis similar to that carried out for  $\mathbb{P}^r$  in [G-P]. As was the case for  $\mathbb{P}^r$ , the fixed part  $\mathcal{T}^{2,f}$  vanishes. So the fixed stack is smooth with tangent bundle  $\mathcal{T}^{1,f}$ . In particular  $[\mathfrak{M}_{\Gamma_1}]^{\text{vir}} = [\mathfrak{M}_{\Gamma_1}]$ . As a result, denoting the contributions from the edges, vertices and flags of the graph  $\Gamma_1$  by  $e_{\Gamma_1}^e, e_{\Gamma_1}^v, e_{\Gamma_1}^F$  respectively, we obtain

$$e(N_{\Gamma_1}^{\text{vir}}) = e_{\Gamma_1}^e \cdot e_{\Gamma_1}^v \cdot e_{\Gamma_1}^F. \tag{4.18}$$

First of all, we have  $e_{\Gamma_1}^e = \prod_e e(\chi(((f|_{C_e})^*T_{X^{[3]}})^{\text{m}}))$  where  $((f|_{C_e})^*T_{X^{[3]}})^{\text{m}}$  denotes the moving part in  $(f|_{C_e})^*T_{X^{[3]}}$ . It follows from (4.10) that

$$e_{\Gamma_1}^e = \prod_e \frac{(-1)^{d_e-1}((d_e - 1)!)^2 w_i w_j z_i z_j (w_i - z_i)^2}{(w_i + z_i)P(1 + \frac{2d_e w_i}{-w_i + z_i}, d_e - 1)P(1 - \frac{d_e(w_i + z_i)}{w_i - z_i}, d_e - 1)} \tag{4.19}$$

where  $P(a, n)$  denotes the polynomial  $a(a + 1) \dots (a + n - 1)$ .

Now the contributions of vertices and flags are given by

$$e_{\Gamma_1}^v = \prod_v e(T_{\Sigma(v)}) \cdot \prod_{\text{val}(v)=n(v)=2} (\omega_{F_1(v)} + \omega_{F_2(v)}) \cdot \prod_{\text{val}(v)=n(v)=1} \omega_{F(v)}^{-1} \tag{4.20}$$

$$e_{\Gamma_1}^F = \prod_{n(F) \geq 3} (\omega_F - e_F) \cdot \prod_F e(T_{i(F)})^{-1} \tag{4.21}$$

where for a flag  $F = (v, e)$ , we put  $\omega_F = e(T_{i(F)}C_{i,j})/d_e$ , and define  $e_F$  to be the first Chern class of the bundle on  $M_{\Gamma}$  whose fiber is the cotangent space of the component associated to  $v$  at the point corresponding to the flag  $F$  (c.f. [C-K, p.285]). Note that  $T_{i(F)} = T_{\Sigma(v)}$  has been computed in (4.8) and (4.9). Thus,  $\omega_F = (-w_i + z_i)/d_e$  if  $i(F) = R_{i,j}^{(1)}$ , and  $\omega_F = (w_i - z_i)/d_e$  if  $i(F) = R_{i,j}^{(2)}$ .

**4.5. Computation of  $T'_{d,i}$ .** Recall from (4.14) and (4.11) that  $T'_{d,i}$  is the set of all stable graphs  $\Gamma$  such that  $f(C) \subset C_{0,1}^{(i)} \cup C_{0,2}^{(i)} \cup C_{1,2}^{(i)}$  for every  $[f : (C; p_1, p_2) \rightarrow X^{[3]}] \in \mathfrak{M}_\Gamma$ , and that the marked vertices of  $\Gamma$  have distinct labels in  $(X^{[3]})^T$ . The  $T$ -fixed points in  $C_{0,1}^{(i)} \cup C_{0,2}^{(i)} \cup C_{1,2}^{(i)}$  are  $Q_{i,0}, Q_{i,1}, Q_{i,2}$ . For  $0 \leq j < k \leq 2$ , let  $T'_{d,i,j,k}$  be the subset of  $T'_{d,i}$  consisting of all  $\Gamma \in T'_{d,i}$  such that the labeling  $\mathfrak{L}$  maps the marked vertices of  $\Gamma$  to  $\{Q_{i,j}, Q_{i,k}\}$ . Then,  $T'_{d,i,0,1}, T'_{d,i,0,2}$  and  $T'_{d,i,1,2}$  form a partition of  $T'_{d,i}$ . So

$$\sum_{\Gamma \in T'_{d,i}} = \sum_{\Gamma \in T'_{d,i,0,1}} + \sum_{\Gamma \in T'_{d,i,0,2}} + \sum_{\Gamma \in T'_{d,i,1,2}}. \tag{4.22}$$

Put  $T''_{d,i,j,k} = T'_{d,i,j,k} / \sim$  where the relation  $\sim$  is defined the same way as in the first paragraph of subsection 4.4. As in (4.17) and (4.16), we get

$$\sum_{\Gamma \in T''_{d,i,j,k}} \int_{[M_\Gamma]^{\text{vir}}} \frac{(A \otimes B)_\Gamma - (1_X \otimes AB)_\Gamma}{|\mathbf{A}_\Gamma| e(N_\Gamma^{\text{vir}})} = \gamma_{i,j,k} \cdot f_{d,i,j,k} \tag{4.23}$$

where  $\gamma_{i,j,k} = -(A|_{Q_{i,j}} - A|_{Q_{i,k}})(B|_{Q_{i,j}} - B|_{Q_{i,k}})$  and

$$f_{d,i,j,k} = \sum_{\Gamma \in T''_{d,i,j,k}} \int_{[M_{\Gamma_1}]^{\text{vir}}} \frac{1}{|\mathbf{A}_{\Gamma_1}| e(N_{\Gamma_1}^{\text{vir}})}. \tag{4.24}$$

By Lemma 4.2, we have  $\gamma_{i,0,1} = -3g_i(w_i^2 + 2w_i z_i - 8z_i^2)^2$ ,  $\gamma_{i,0,2} = -3g_i(-8w_i^2 + 2w_i z_i + z_i^2)^2$  and  $\gamma_{i,1,2} = -243g_i(w_i^2 - z_i^2)^2$ . Combining (4.22) and (4.23) yields

$$\begin{aligned} T'_{d,i} &= \sum_{\Gamma \in T'_{d,i}} \int_{[\mathfrak{M}_\Gamma]^{\text{vir}}} \frac{(A \otimes B)_\Gamma - (1_X \otimes AB)_\Gamma}{e(N_\Gamma^{\text{vir}})} \\ &= \gamma_{i,0,1} \cdot f_{d,i,0,1} + \gamma_{i,0,2} \cdot f_{d,i,0,2} + \gamma_{i,1,2} \cdot f_{d,i,1,2}. \end{aligned} \tag{4.25}$$

The  $f_{d,i,j,k}$  can be calculated via graph sums in a manner similar to the calculation of the  $e_{d,i,j}$  in subsection 4.4. Note that if  $f_{d,i,0,1}$  is written as a function of the variables  $w_i$  and  $z_i$ , then  $f_{d,i,0,2}$  can be obtained from  $f_{d,i,0,1}$  by switching  $w_i$  and  $z_i$ . Also, for an edge  $e$  of a stable graph  $\Gamma$  and for  $0 \leq j < k \leq 2$ , define  $e \in [Q_{i,j}Q_{i,k}]$  if the labeling  $\mathfrak{L}$  of  $T$  maps the two vertices of  $e$  to the set  $\{Q_{i,j}, Q_{i,k}\}$ . By Lemma 4.1, the curves  $C_{0,1}^{(i)}, C_{0,2}^{(i)}$  and  $C_{1,2}^{(i)}$  are homologous to  $\beta_3, \beta_3$  and  $3\beta_3$  respectively. Therefore, for each stable graph  $\Gamma$ , the edges  $e$  satisfy

$$\sum_{e \in [Q_{i,0}Q_{i,1}]} d_e + \sum_{e \in [Q_{i,0}Q_{i,2}]} d_e + \sum_{e \in [Q_{i,1}Q_{i,2}]} 3d_e = d. \tag{4.26}$$

**4.6. Cases when  $1 \leq d \leq 4$ .** When the degree  $d$  is small, we can use Mathematica and the setups of subsections 4.4 and 4.5 to make explicite computations. We now do this for  $1 \leq d \leq 4$ .

When  $1 \leq d \leq 4$ , we have verified via Mathematica that

$$e_{d,i,j} = \frac{w_i + z_i}{dw_i w_j (w_i - z_i)^2 z_i z_j} \quad \text{and} \quad S'_{d,i,j} = \frac{(2g_i + g_j)(w_i + z_i)^3}{dw_i w_j z_i z_j}. \tag{4.27}$$

Unfortunately, we are not able to prove this formula for general  $d$ .

Also, for  $1 \leq d \leq 4$ , the functions  $f_{d,i,0,1}$  are given by

$$f_{1,i,0,1} = \frac{w_i + z_i}{w_i(w_i - 2z_i)^2(w_i - z_i)z_i^2} \tag{4.28}$$

$$\begin{aligned} f_{2,i,0,1} &= \frac{2w_i^2 + 7w_iz_i + 5z_i^2}{2w_i(w_i - 2z_i)^2(w_i - z_i)(2w_i - z_i)z_i^2} \\ &= \frac{1}{2}f_{1,i,0,1} + \frac{3(w_i + z_i)}{w_i(w_i - 2z_i)^2(w_i - z_i)(2w_i - z_i)z_i} \end{aligned} \tag{4.29}$$

$$\begin{aligned} f_{3,i,0,1} &= \frac{2(w_i + z_i)(w_i + 4z_i)}{3w_i(w_i - 2z_i)^2(w_i - z_i)(2w_i - z_i)z_i^2} \\ &= \frac{1}{3}f_{1,i,0,1} + \frac{3(w_i + z_i)}{w_i(w_i - 2z_i)^2(w_i - z_i)(2w_i - z_i)z_i} \end{aligned} \tag{4.30}$$

$$\begin{aligned} f_{4,i,0,1} &= \frac{2w_i^2 + 7w_iz_i + 5z_i^2}{4w_i(w_i - 2z_i)^2(w_i - z_i)(2w_i - z_i)z_i^2} \\ &= \frac{1}{4}f_{1,i,0,1} + \frac{3(w_i + z_i)}{2w_i(w_i - 2z_i)^2(w_i - z_i)(2w_i - z_i)z_i} \end{aligned} \tag{4.31}$$

Recall that if we regard  $f_{d,i,0,1}$  as a function of  $z_i$  and  $w_i$ , then  $f_{d,i,0,2}$  can be obtained from  $f_{d,i,0,1}$  by switching  $z_i$  and  $w_i$ . So  $f_{d,i,0,2}$  is known for  $1 \leq d \leq 4$ . Furthermore,

$$f_{1,i,1,2} = 0 \tag{4.32}$$

$$f_{2,i,1,2} = \frac{w_i + z_i}{w_i(w_i - 2z_i)(w_i - z_i)^2(2w_i - z_i)z_i} \tag{4.33}$$

$$f_{3,i,1,2} = \frac{w_i + z_i}{w_i(w_i - 2z_i)(w_i - z_i)^2(2w_i - z_i)z_i} \tag{4.34}$$

$$f_{4,i,1,2} = \frac{w_i + z_i}{2w_i(w_i - 2z_i)(w_i - z_i)^2(2w_i - z_i)z_i}. \tag{4.35}$$

Combining formulas (4.28)-(4.35) with (4.25), we conclude that

$$T'_{1,i} = \frac{-3g_i(w_i^3 - 6w_i^2z_i - 6w_iz_i^2 + z_i^3)}{w_i^2z_i^2} \tag{4.36}$$

$$T'_{2,i} = \frac{-3g_i(w_i^3 + 12w_i^2z_i + 12w_iz_i^2 + z_i^3)}{2w_i^2z_i^2} = \frac{1}{2}T'_{1,i} - \frac{27g_i(w_i + z_i)}{w_iz_i} \tag{4.37}$$

$$T'_{3,i} = \frac{-3g_i(w_i^3 + 21w_i^2z_i + 21w_iz_i^2 + z_i^3)}{3w_i^2z_i^2} = \frac{1}{3}T'_{1,i} - \frac{27g_i(w_i + z_i)}{w_iz_i} \tag{4.38}$$

$$T'_{4,i} = \frac{-3g_i(w_i^3 + 12w_i^2z_i + 12w_iz_i^2 + z_i^3)}{4w_i^2z_i^2} = \frac{1}{4}T'_{1,i} - \frac{27g_i(w_i + z_i)}{2w_iz_i}. \tag{4.39}$$

In view of formulas (4.15), (4.27) and (4.36)-(4.39), we obtain

$$\langle A, B \rangle_{0,1} = -81 \tag{4.40}$$

$$\langle A, B \rangle_{0,2} = -\frac{81}{2} + 81 = \frac{81}{2} \tag{4.41}$$

$$\langle A, B \rangle_{0,3} = -\frac{81}{3} + 81 = 54 \tag{4.42}$$

$$\langle A, B \rangle_{0,4} = -\frac{81}{4} + \frac{81}{2} = \frac{81}{4}. \tag{4.43}$$

PROPOSITION 4.3. *Let  $X = \mathbb{P}^2$ , and  $\ell \subset X$  be a line. Then, the 2-point genus-0 Gromov-Witten invariant  $\langle \text{PD}(\mathfrak{a}_{-3}(\ell)|0), \text{PD}(\mathfrak{a}_{-3}(X)|0) \rangle_{0,d}$  is equal to  $-27$ ,  $27/2$ ,  $18$  and  $27/4$  when  $d$  is equal to  $1$ ,  $2$ ,  $3$  and  $4$  respectively.*

*Proof.* Follows immediately from (4.12) and (4.40)-(4.43).  $\square$
