Abstract

Let $Y$ be the zero loci of a regular section of a convex vector bundle $E$ over $X$. We provide a proof of a conjecture of Cox, Katz and Lee for the virtual class of the genus zero moduli of stable maps to $Y$. This in turn yields the expected relationship between Gromov-Witten theories of $Y$ and $X$ which together with Mirror Theorems allows for the calculation of enumerative invariants of $Y$ inside of $X$.

1991 Mathematics Subject Classification. Primary 14N35. Secondary 14C17.
Introduction

Let $X$ be a smooth, projective variety over $\mathbb{C}$. A vector bundle $E \to X$ is called convex if $H^1(f^*(E)) = 0$ for any nonconstant morphism $f : \mathbb{P}^1 \to X$. Let $Y = Z(s) \subset X$ be the zero locus of a regular section $s$ of a convex vector bundle $E$ and let $i$ denote the embedding of $Y$ in $X$. It is the relationship between the Gromov-Witten theories of $Y$ and $X$ that we study here.

0.1 Virtual class of the zero loci

Let $\overline{M}_{0,n}(X, d)$ be the $\mathbb{Q}$-scheme that represents coarsely genus zero, $n$-pointed stable maps $(C, x_1, x_2, \ldots, x_n, f : C \to X)$ of class $d \in H^2(X, \mathbb{Z})$. Since $E$ is convex the vector spaces $H^0(f^*(E))$ fit into a $\mathbb{Q}$-vector bundle $E_d$ on $\overline{M}_{0,n}(X, d)$. The section $s$ of $E$ induces a section $\tilde{s}$ of $E_d$ over $\overline{M}_{0,0}(X, d)$ via $\tilde{s}(\langle C, f \rangle) = s \circ f$. If $i_*(\beta) = d$ the map $i : Y \hookrightarrow X$ yields an inclusion $i_\beta : \overline{M}_{0,0}(Y, \beta) \to \overline{M}_{0,0}(X, d)$. Clearly

$$Z(\tilde{s}) = \bigsqcup_{i_* \beta = d} \overline{M}_{0,0}(Y, \beta).$$

The map $i_* : H_2(Y) \to H_2 X$ is not injective in general, hence the zero locus $Z(\tilde{s})$ may have more than one connected component. An example is the quadric surface in $\mathbb{P}^3$.

The $\mathbb{Q}$-normal bundle of $Z(\tilde{s})$ in $\overline{M}_{0,0}(X, d)$ is $E_d|_{Z(\tilde{s})}$. In Section 2.1 of this paper we prove the following theorem [5]

**Theorem 0.1.1.** For any $d \in H^2(X, \mathbb{Z})$,

$$\sum_{i_* \beta = d} (i_\beta)_*[\overline{M}_{0,0}(Y, \beta)]^{vir} = c_{top}(E_d) \cap [\overline{M}_{0,0}(X, d)]^{vir}.$$

where $c_{top}$ denotes the top Chern operator. The first proof appeared in [10] and uses Behrend-Fantechi construction of the virtual fundamental class. Our approach is based on the alternative Tian-Lian construction.
Remark 0.1.1. Theorem 0.1.1 was conjectured in [5] in the language of
stacks. It is easily seen that our formulation is equivalent to the stack one,
at least from a point of view of calculations. The original conjecture is stated
for any \( n \)-pointed moduli stack. But one of the functorial properties of the
virtual class is that
\[
\pi^{*}([M_{0,n-1}(Y,\beta)]_{\text{virt}}) = [M_{0,n}(Y,\beta)]_{\text{virt}}.
\]
It is also true that \( \pi^{*}_{n+1}(E_{d}) = E_{d} \) [6]. Suffices then to prove the theorem
for 0-pointed stable maps.

0.2 Mirror Theorems

Theorem 0.1.1 together with Mirror Theorem provide a complete answer to
the relationship between the enumerative invariants of \( Y \) and those of \( X \).

Let \( \{T_{0} = 1, T_{1}, ..., T_{m}\} \) a basis of \( H^{*}(Y,\mathbb{Q}) \) such that Span\( \{T_{1}, ..., T_{r}\} = H^{2}(Y,\mathbb{Q}) \). Let \( t_{1}, ..., t_{r} \) be variables and \( tT = \sum_{i=1}^{r} t_{i}T_{i} \). We denote by \( e \) the
cotangent line class on \( \overline{M}_{0,1}(Y,\beta) \), i.e. the first chern class of the line bundle
whose fiber over moduli point \( (C, x_{1}, f) \) is \( T_{C,x_{1}}^{\vee} \). Let \( e \) be the evaluation
map on \( \overline{M}_{0,1}(Y,\beta) \). Let \( h \) be a formal parameter. Then the quantum \( D \)-
module structure of the pure quantum cohomology of \( Y \) is determined by
the following formal function [8]:
\[
J_{Y} := e^{tT} \cap \left( 1 + \sum_{0 \neq \beta \in H_{2}(Y,\mathbb{Z})} q^{\beta} c_{*} \left( \frac{[M_{0,1}(Y,\beta)]_{\text{vir}}}{h(h - c)} \right) \right). \tag{1}
\]
Note that \( e^{tT} \) acts via its power series expansion (which is finite). For
our purposes \( J_{Y} \) will be viewed as an element of the Novikov completion
\( H_{*}Y[[t_{1}, ..., t_{r}, h^{-1}]] [[q^{\beta}]] \) of the ring \( H_{*}Y[[t_{1}, ..., t_{r}, h^{-1}]] \) along the semigroup
of rational curves \( \beta \) in \( Y \). This generator encodes Gromov-Witten invariants
and gravitational descendants of \( Y \).

For each stable map \( (C, x_{1}, f) \in \overline{M}_{0,1}(X,d) \) the sections of \( H^{0}(C, f^{*}(E)) \)
that vanish at \( x_{1} \) form a bundle \( E'_{d} \) that fits into an exact sequence:
\[
0 \to E'_{d} \to E_{d} \to e^{*}(E) \to 0 \tag{2}
\]

The quantum \( D \)-module structure of the \( E \)-twisted quantum cohomology
of \( X \) [6][8] is determined by the following formal function:
\[
J_{E} := e^{tT'} c_{\text{top}}(E) \cap \left( 1 + \sum_{0 \neq d \in H_{2}(X,\mathbb{Z})} q^{d} c_{*} \left( \frac{c_{\text{top}}(E'_{d}) \cap [\overline{M}_{0,1}(X,d)]_{\text{vir}}}{h(h - c)} \right) \right).
\]
where \( tT' \) and \( c \) denote similar expressions to those in \( J_Y \). Mirror theorem states that for a large class of smooth varieties \( X \), the generator \( J_E \) is computable via hypergeometric series \([2],[6],[8],[11]\). While important in itself, this fact is relevant with respect to the Gromov-Witten theory of \( Y \) only if one can show that \( J_E \) is intrinsically related to \( Y \). The basic example is when \( X \) is a projective bundle and \( E \) is a direct sum positive line bundles. It has been shown in \([4]\) that in this case \( i^*(J_Y) = J_E \). Coupled with the fact that \( J_E \) is computable this allows for the calculation of (at least some of) gravitational descendants of \( Y \). This is for example how one computes the enumerative invariants of the quintic threefold. In section 2.2 we use Theorem 0.1.1 to prove the following generalization: Assume that the map \( i_* : H^2(Y) \to H^2(X) \) is surjective. Complete a basis \( \{T'_1, T'_2, ..., T'_r\} \) of \( H^2X \) into a basis \( \{T_1 = i^*(T'_1), ..., T_r = i^*(T'_r), ..., T_m\} \) of \( H^2Y \). We extend the map \( i_* : H_*Y \to H_*X \) to a homomorphism of completions \( i_* : H_*Y[[t_1, ..., t_m, h^{-1}]][[q^\beta]] \to H_*X[[t_1, ..., t_r, h^{-1}]][[q^d]] \) via \( i_*(t_k) = 0 \) for \( k > r \) and \( i_*(q^\beta) = q^{i^*(\beta)} \).

**Theorem 0.2.1.** Assume that \( i_* : H^2(Y) \to H^2(X) \) is surjective. Then \( i_*(J_Y) = J_E \).

## 1 Background

### 1.1 Stable maps and Gromov-Witten invariants

Let \( g, n \) nonnegative numbers and \( d \in H^2(X, \mathbb{Z}) \). A stable map of genus \( g \) with \( n \)-markings consists of a nodal curve \( C \), an \( n \)-tuple \( (x_1, x_2, ..., x_n) \) of smooth points of \( C \) and a map \( f : C \to X \) that has a finite group of automorphisms. A stable map \( (C, x_1, ..., x_n, f) \) is said to represent the curve class \( d \) if \( f_*[C] = d \). The moduli functor that parameterizes such stable maps is a proper Deligne-Mumford stack \( \mathcal{M}_{g,n}(X, d) \) and is coarsely represented by a \( \mathbb{Q} \)-scheme denoted by \( \overline{\mathcal{M}}_{g,n}(X, d) \) (see section 1.3 for a discussion on the category of \( \mathbb{Q} \)-schemes). The expected dimension of this moduli stack is \( (\dim X - 3)(1-g) + n - K_X \cdot \beta \). Let \( x_k \) be one of the marked points. The evaluation morphism \( e_k : \overline{\mathcal{M}}_{g,n}(X, d) \to X \) sends a closed point \( (C, x_1, ..., x_n, f) \) to \( f(x_k) \). The contangent bundle at \( x_k \) is denoted by \( \mathcal{L}_k \). Its fiber over the closed point \( (C, x_1, ..., x_n, f) \) is \( T_{C, x_k}^\vee \). The forgetful morphism \( \pi_k : \overline{\mathcal{M}}_{g,n+1}(X, d) \to \overline{\mathcal{M}}_{g,n}(X, d) \) forgets the \( k \)-th marking and stabilizes the
source curve. The universal stable map over \( \overline{M}_{g,n}(X,d) \) is
\[
\begin{array}{c}
\overline{M}_{g,n+1}(X,d) \\
\pi_{n+1}
\end{array}
\xrightarrow{\epsilon_{n+1}} X
\]
\[
\overline{M}_{g,n}(X,d).
\]
The bundle \( E_d \) from the introduction may be precisely defined as \( E_d := \pi_{n+1}^* e_{n+1}^*(E) \).

### 1.2 The virtual fundamental class and the associativity of the refined Gysin maps

The moduli spaces of stable maps may behave badly in families and they may have components whose dimension is bigger than the expected dimension. However there is a cycle of the expected dimension either in the Chow ring of the stack [1] or in the Chow ring of the coarse moduli space [13] which is deformation invariant. This class is used instead of the true fundamental class for intersection theory purposes. In this section we review the Li-Tian construction of the virtual fundamental class and a key lemma about the associativity of the refined Gysin maps.

The virtual fundamental class of a moduli functor is constructed in general using solely a choice of a tangent-obstruction complex. Our interest here is the moduli functor \( \mathcal{F}_X^d \) of 0-pointed, genus zero, degree \( d \) stable maps to \( X \). We describe the natural tangent-obstruction complex of \( \mathcal{F}_X^d \). Let \( \eta \in \mathcal{F}_X^d(S) \) be represented by the following diagram
\[
\begin{array}{c}
\mathcal{X} \\
\pi
\end{array}
\xrightarrow{f} X
\]
\[
S
\]

The deformations and obstructions of \( \eta \) are described respectively by the global sections of the sheaves \( T^1 \mathcal{F}_X^d(\eta) := \mathcal{E}xt^1_{\mathcal{X}/S}([f^*\Omega_X \to \Omega_{\mathcal{X}/S}], \mathcal{O}_{\mathcal{X}}) \) and \( T^2 \mathcal{F}_X^d(\eta) := \mathcal{E}xt^2_{\mathcal{X}/S}([f^*\Omega_X \to \Omega_{\mathcal{X}/S}], \mathcal{O}_{\mathcal{X}}) \). The natural tangent obstruction-complex for this moduli problem is \( T^\bullet \eta := [T^1 \mathcal{F}_X(\eta) \to T^2 \mathcal{F}_X(\eta)] \) with the zero arrow. This complex is perfect in the sense that locally, there is a 2-term complex of locally free sheaves \( E^\bullet_{\eta} := [E_{\eta,1} \to E_{\eta,2}] \) whose sheaf cohomology yields the tangent-obstruction complex \( H^\bullet E^\bullet_{\eta} = T^\bullet \eta \).

The virtual fundamental class of \( T^\bullet \eta \) is a Chow class in the Chow ring of the \( \mathbb{Q} \)-scheme \( \overline{M}_{g,n}(X,d) \). We denote it by \( \overline{[M}_{g,n}(X,d)]^{\vir} \). This class corresponds under Poincaré duality to \( 1 \in H^*(\overline{M}_{g,n}(X,d)) \).
The key to the proof of Theorem 0.1.1 is a lemma about the associativity of the refined Gysin maps. Let us first formulate it for representable functors. Consider a fibre diagram

\[
\begin{array}{ccc}
W_0 & \xrightarrow{\delta_0} & W \\
\downarrow{\alpha_0} & & \downarrow{\alpha} \\
T_0 & \xrightarrow{\delta} & T
\end{array}
\]

(3)

where \( \delta \) is a regular embedding. Let \( \mathcal{N} \) be the normal bundle of \( T_0 \) in \( T \). Assume that \( W \) and \( W_0 \) admit perfect tangent obstruction-complexes \( T^\bullet_W \) and \( T^\bullet_{W_0} \). They are said to be compatible relative to the fibre diagram (3) if for each affine scheme \( S \) and for any morphism \( \eta : S \to W_0 \subset W \) there is an exact sequence

\[
0 \to T^1_W(\eta) \to T^1_{W_0}(\eta) \to (\alpha_0 \circ \eta)^*\mathcal{N} \to T^2_{W_0}(\eta) \to T^2_W(\eta) \to 0. \quad (4)
\]

Assume that this compatibility satisfies a technical condition. Namely, there exists a short exact sequence of 2-term complexes

\[
0 \to [0 \to (\alpha_0)^*\mathcal{N}] \to E^\bullet_\eta \to E^\bullet_\eta \to 0 \quad (5)
\]

such that

- Its long exact sequence of cohomologies is precisely the exact sequence of the compatibility.
- The cohomologies of \( E^\bullet_\eta \) and \( E^\bullet_\eta \) yield the tangent-obstruction complex of \( W_0 \).

**Proposition 1.2.1.** [13] Assume that \( T^\bullet_W \) and \( T^\bullet_{W_0} \) are compatible and the technical condition (5) is satisfied. Then

\[
\delta_0^![W]^{\text{vir}} = [W_0]^{\text{vir}}
\]

where the virtual cycles are with respect to \( T^\bullet_W \) and \( T^\bullet_{W_0} \).

The case of interest for us is the localized top chern class [7] of \((E, s)\), where \( E \to Z \) is a vector bundle and \( s \) is a section of \( E \). We use diagram (3) with \( T_0 = W = Z \) and \( T \) the total space of \( E \). Let \( \delta = s_E \) be the zero section of \( E \) and \( \alpha = s \). It follows that \( W_0 = Z(s) \) is the zero locus of \( s \).

**Corollary 1.2.1.** With the assumptions of the previous proposition

\[
\alpha_0^*[Z(s)]^{\text{vir}} = c_{\text{top}}(E) \cap [Z]^{\text{vir}} \quad (6)
\]
1.3 The category of \(\mathbb{Q}\)-schemes

Stable maps have nontrivial automorphisms hence the moduli functor of stable maps is only locally representable. It follows that in dealing with virtual fundamental class and Gromov-Witten invariants one has to work either in the category of \(\mathbb{Q}\)-schemes or in the category of stacks. We chose to work in the category of \(\mathbb{Q}\)-schemes after a failed attempt to prove a stack version of Proposition 1.2.1. Such a version has since appeared in [10]. The category of \(\mathbb{Q}\)-schemes is a natural generalization of Mumford’s notion of \(\mathbb{Q}\)-varieties. In the étale topology, \(\mathbb{Q}\)-schemes look like finite quotients of quasiprojective schemes. The precise definition is due to Lian-Tian.

**Definition 1.3.1.** A \(\mathbb{Q}\)-scheme is a scheme \(U\) together with the following data:

- A finite collection \((U_\alpha, G_\alpha, q_\alpha)\) where \(U_\alpha\) is a quasi-projective scheme, \(G_\alpha\) is a finite group acting on \(U_\alpha\) and \(q_\alpha : U_\alpha/G_\alpha \to U\) is an étale map such that \(U = \cup \text{Im}(q_\alpha)\).

- For each pair of indices \((\alpha, \beta)\) there is 
  \[
  (U_{(\alpha,\beta)}, G_{(\alpha,\beta)} = G_\alpha \times G_\beta, q_{(\alpha,\beta)})
  \]
  together with with equivariant finite étale maps
  \[U_{(\alpha,\beta)} \to U_\alpha, U_{(\alpha,\beta)} \to U_\beta\]
  such that \(\text{Im}q_{(\alpha,\beta)}) = \text{Im}q_\alpha \cap \text{Im}q_\beta\) and the map \(q_{(\alpha,\beta)}\) factors through both \(q_\alpha\) and \(q_\beta\) via the above maps.

- For any triple \((\alpha, \beta, \gamma)\) there is \((U_{(\alpha,\beta,\gamma)}, G_{(\alpha,\beta,\gamma)}, q_{(\alpha,\beta,\gamma)})\) with \(G_{(\alpha,\beta,\gamma)} = G_\alpha \times G_\beta \times G_\gamma\) together with equivariant, finite, étale maps from \(U_{(\alpha,\beta,\gamma)}\) to \(U_{(\alpha,\beta)}, U_{(\alpha,\gamma)}, U_{(\beta,\gamma)}\) which commute with the maps introduced in the second condition and such that
  \[\text{Im}q_{(\alpha,\beta,\gamma)} = \text{Im}q_\alpha \cap \text{Im}q_\beta \cap \text{Im}q_\gamma.\]

Features such as morphisms, sheaves, cones in the category of \(\mathbb{Q}\)-schemes are defined as equivariant local objects that descend to the level of \(\mathbb{Q}\)-schemes. Using this recipe we define \(\mathbb{Q}\)-sheaves and \(\mathbb{Q}\)-complexes on a \(\mathbb{Q}\)-scheme. The chern classes of a \(\mathbb{Q}\)-bundle \(E\) on a \(\mathbb{Q}\)-scheme \(U\) may be defined as cohomology classes with rational coefficients by imitating the definition of the chern classes of vector bundles on Deligne-Mumford stacks. They are the chern classes of the \(\mathbb{Q}\)-cone on \(U\) obtained by the patching of the
$G_\alpha$-quotients of $E$ on $U_\alpha$. Let $s$ be a section of $E$ given locally by $s_\alpha$. The zero locus $Z(s)$ is a closed $\mathbb{Q}$-subscheme of $U$ with chart $Z(s_\alpha) \cap U_\alpha$. The localized top Chern class of $(E,s)$ may be defined by imitating the construction of Fulton [7] as follows. Let $F$ be a pure $n$-dimensional subscheme of $U$. The group $G_\alpha$ acts on the normal cone to $Z(s_\alpha) \cap q_\alpha^{-1}(F)$ in $q_\alpha^{-1}(F)$. The quotients can be patched together to a $\mathbb{Q}$-cone $C_{Z(s)/F}$ inside of the restriction to $Z(s)$ of the $\mathbb{Q}$-bundle $E$. Let $i$ be the zero section of this cone. Then the action of the localized top Chern class of $(E,s)$ on $F$ is $i^*[C_{Z(s)/F}]$.

One can easily check that, with this definition, Corollary 1.2.1 holds. The technical assumption is the same; the only difference is that the complexes become $\mathbb{Q}$-complexes.

2 The Proofs

2.1 The associativity of the refined Gysin maps in the category of $\mathbb{Q}$-schemes.

It is known that $\overline{M}_{0,0}(X,d)$ has a $\mathbb{Q}$-scheme structure so that the functors $\text{Hom}(-,\overline{M}_{0,0}(X,d))$ and $\mathcal{F}_X^q$ are equivalent. Here is a brief sketch. Let $(C,f) \in \overline{M}_{0,0}(X,d)$ be a stable map. Choose divisors $H_1,H_2,\ldots,H_r$ so that $f$ intersects each $H_i$ transversally at $y_{i1},\ldots,y_{id_i}$ and $(\tilde{C},y_{ij})$ has no automorphisms. Now $\text{Aut}(f)$ acts on $(\tilde{C},f) \in \overline{M}_{0,0}(dr)(X,d) \cap e^{*}_{ij}(H_i)$ by permuting the markings. Choose a quasiprojective $\text{Aut}(f)$-equivariant neighborhood $U_f \subset \overline{M}_{0,dr}(X,d) \cap e^{*}_{ij}(H_i)$ of $(\tilde{C},f)$ such that all the stable maps in $U_f$ have no automorphisms and the map that forgets the markings does not change the source curve. There is an action of $\text{Aut}(f)$ on the universal stable map $(\mathcal{C}_f,F_f)$ over $U_f$. The classifying map $U_f/\text{Aut}(f) \to \overline{M}_{0,0}(X,d)$ is étale. The neighborhoods $U_f$ satisfy the conditions of a $\mathbb{Q}$-scheme.

It has been pointed out in [13] that the virtual fundamental class can be constructed alternatively as follows: First, one constructs a local virtual class $[U_f]^{\text{vir}}$ using the tangent-obstruction complex of the universal family over $U_f$. Then the $Aut_f$-quotients of these local virtual classes patch to the virtual class $[\overline{M}_{0,0}(X,d)]^{\text{vir}}$. Clearly, the group $Aut_f$ acts on the restriction of the universal family $(\mathcal{C}_f,F_f)$ over $U_f^s := Z(\tilde{s}) \cap U_f$ and the classifying map $U_f^s/\text{Aut}(f) \to Z(\tilde{s})$ is again étale. The local Gysin diagrams (3) patch to a global Gysin diagram in the category of $\mathbb{Q}$-schemes. Of crucial importance for us is that Corollary 1.2.1 holds in the category of $\mathbb{Q}$-schemes.
2.2 Virtual class of the zero loci

The proof of theorem 0.1.1 uses corollary 1.2.1. We need to check that the technical condition is satisfied. Let η be a 0-pointed, genus zero stable map of class d over an affine scheme S represented by the following diagram

\[
\begin{array}{ccc}
\mathcal{X} & \xrightarrow{f} & Y \\
\downarrow \pi & & \downarrow \iota \\
S & & X 
\end{array}
\]

The deformations and obstructions of η are described respectively by the global sections of the sheaves \( T^1 \mathcal{F}^d_X(\eta) := \mathcal{E}xt^1_{\mathcal{X}/S}([f^*(\Omega_X) \to \Omega_{X/S}], \mathcal{O}_X) \) and \( T^2 \mathcal{F}^d_X(\eta) := \mathcal{E}xt^2_{\mathcal{X}/S}([f^*(\Omega_X) \to \Omega_{X/S}], \mathcal{O}_X) \). Since the normal bundle of Y in X is \( E|_Y \) the conormal exact sequence writes

\[
0 \to f^*(E^*|_Y) \to f^*(\Omega_X|_Y) \to f^*(\Omega_Y) \to 0 \quad (7)
\]

Recall from [13] that there is a short exact sequence of \( \mathcal{O}_\mathcal{X} \)-sheaves

\[
0 \to W_2 \to W_1 \to f^*\Omega_X \to 0 \quad (8)
\]

such that:

- \( \mathcal{E}xt^i_{\mathcal{X}/S}([W_1 \to \Omega_{\mathcal{X}/S}], \mathcal{O}_\mathcal{X}) \) and \( \mathcal{E}xt^i([W_2 \to 0], \mathcal{O}_\mathcal{X}) \) vanish for \( i \neq 1 \).

- Both \( \mathcal{E}_{\eta,1} = \mathcal{E}xt^1_{\mathcal{X}/S}([W_1 \to \Omega_{\mathcal{X}/S}], \mathcal{O}_\mathcal{X}) \) and \( \mathcal{E}_{\eta,2} = \mathcal{E}xt^1([W_2 \to 0], \mathcal{O}_\mathcal{X}) \) are locally free.

- The sheaf cohomology of the complex \( \mathcal{E}_\eta^\bullet = [\mathcal{E}_{\eta,1} \to \mathcal{E}_{\eta,2}] \) is the tangent-obstruction complex of the stable map η, i.e. there is an exact sequence

\[
0 \to T^1 \mathcal{F}^d_X(\eta) \to \mathcal{E}_{\eta,1} \to \mathcal{E}_{\eta,2} \to T^2 \mathcal{F}^d_X(\eta) \to 0.
\]

We pull back (8) exact sequence via (7) and obtain the following diagram
Let $\tilde{\mathcal{E}}_{\eta,2} := \text{Ext}^1_{X/S}([A \to 0], \mathcal{O}_X)$. We apply the long exact sequence for $\text{Ext}$ to various exact sequences obtained from the above diagram. The middle vertical sequence yields a short exact sequence

$$0 \to [A \to 0] \to [W_1 \to \Omega_{X/S}] \to [f^*(\Omega_Y) \to \Omega_{X/S}] \to 0.$$  

Its long exact sequence for $\text{Ext}$ yields

$$0 \to \mathcal{T}^1_{\mathcal{F}^2_Y(\eta)} \to \mathcal{E}_{\eta,1} \to \tilde{\mathcal{E}}_{\eta,2} \to \mathcal{T}^2_{\mathcal{F}^2_Y(\eta)} \to 0.$$  

Let $\tilde{\mathcal{E}}^\bullet_{\eta} := [\mathcal{E}_{\eta,1} \to \tilde{\mathcal{E}}_{\eta,2}]$. The last exact sequence says that the cohomology of $\tilde{\mathcal{E}}^\bullet_{\eta}$ is the tangent obstruction complex of $\eta$. Next, we apply the long exact sequence for $\text{Ext}$ to the top horizontal row of the diagram and use the conditions for $W_i$'s. We obtain

$$0 \to \text{Ext}^1_{X/S}([f^*(E^*) \to 0], \mathcal{O}_X) \to \tilde{\mathcal{E}}_{\eta,2} \to \mathcal{E}_{\eta,2} \to \text{Ext}^2_{X/S}([f^*(E^*) \to 0], \mathcal{O}_X).$$

But one easily sees that

$$\text{Ext}^2_{X/S}([f^*(E^*) \to 0], \mathcal{O}_X) \simeq \text{Ext}^1(f^*(E^*), \mathcal{O}_X) = 0$$

and

$$\text{Ext}^1_{X/S}([f^*(E^*) \to 0], \mathcal{O}_X) \simeq \pi_* f^* (E)$$

as $\mathcal{O}_S$-sheaves. It follows that there is an exact sequence

$$0 \to [0 \to \pi_* (f^*(E))] \to \tilde{\mathcal{E}}_{\eta} \to \mathcal{E}_{\eta}^\bullet \to 0.$$ \hspace{1cm} (9)

Its long exact sequence of sheaf cohomologies is easily seen to be

$$0 \to \mathcal{T}^1_{\mathcal{F}^3_Y(\eta)} \to \mathcal{T}^1_{\mathcal{F}^3_X(\eta)} \to \pi_* f^* E \to \mathcal{T}^2_{\mathcal{F}^3_Y(\eta)} \to \mathcal{T}^2_{\mathcal{F}^3_X(\eta)} \to 0.$$ \hspace{1cm} (10)

The technical condition is satisfied.
2.3 Mirror Theorems

We recall the setup. Let $i$ denote the embedding of $Y$ in $X$. Assume that the map $i_* : H_2(Y) \to H_2(X)$ is surjective. Complete a basis $\{T_1', T_2', ..., T_r'\}$ of $H^2X$ to a basis $\{T_1 := i^*(T_1'), ..., T_r := i^*(T_r'), T_{r+1}, ..., T_m\}$ of $H^2Y$. Let $tT = \sum_{i=1}^m t iT_i$ and $tT' = \sum_{i=1}^r t_i T_i'$ where $t_1, ..., t_n$ are variables. The map $i_* : H_*Y \to H_*X$ extends to a homomorphism of completions

$$i_* : H_*Y[[t_1, ..., t_m, h^{-1}]][[q^\beta]] \to H_*X[[t_1, ..., t_r, h^{-1}]][[q^d]]$$

via $i_*(t_k) = 0$ for $k > r$ and $i_*(q^\beta) = q^{i_*(\beta)}$.

**Theorem 2.3.1.** Assume that $i_* : H_2(Y) \to H_2(X)$ is surjective. Then $i_*(J_Y) = J_E$.

**Proof.** Recall that

$$J_Y := e^{\frac{tT}{\hbar}} \cap \left(1 + \sum_{\beta \neq 0} q^\beta e_* \left(\frac{[M_{0,1}(Y, \beta)]^{\text{vir}}_{\text{vir}}}{h(h-c)}\right)\right)$$

By the definition of $i_*$ and the projection formula we obtain

$$i_*(J_Y) = e^{\frac{tT'}{\hbar}} \cap \left(e_* (1) + \sum_{\beta \neq 0} q^\beta i_* \left(e_* \left(\frac{[M_{0,1}(Y, \beta)]^{\text{vir}}_{\text{vir}}}{h(h-c)}\right)\right)\right)$$

As we have said before any $\beta \in H_2(Y, \mathbb{Z})$ such that $i_*(\beta) = d$ induces a morphism $i_\beta : \overline{M}_{0,0}(Y, \beta) \to \overline{M}_{0,0}(X, d)$. Consider the following commutative diagram:

$$\begin{array}{ccc}
\overline{M}_{0,1}(Y, \beta) & \xrightarrow{i_\beta} & \overline{M}_{0,1}(X, d) \\
\downarrow e & & \downarrow e \\
Y & \xrightarrow{i} & X \\
\end{array}$$

The line bundle $L_1$ on $\overline{M}_{0,1}(Y, \beta)$ is the pullback via $i_\beta$ of the bundle on $\overline{M}_{0,1}(X, d)$. By the projection formula and Theorem 2.0.1:

$$i_* \left(\sum_{i_*(\beta) = d} e_* \left(\frac{[M_{0,1}(Y, \beta)]_{\text{vir}}}{h(h-c)}\right)\right) = e_* \left(\sum_{i_*(\beta) = d} (i_\beta)_* \frac{[M_{0,0}(Y, \beta)]_{\text{vir}}}{h(h-c)}\right)$$

$$= e_* \left(\frac{c_{\text{top}}(E_d) \cap [M_{0,0}(X, d)]_{\text{vir}}}{h(h-c)}\right)$$  \hspace{1cm} (11)
The exact sequence (2) implies

\[ c_{\text{top}}(E_d) = c_{\text{top}}(E'_d)e^*(c_{\text{top}}(E)) \quad (12) \]

hence by the projection formula

\[
i_* \left( \sum_{i_*(\beta) = d} e_* \left( \frac{[\overline{M}_{0,1}(Y, \beta)]^{\mathrm{vir}}}{h(h-c)} \right) \right)
\]

\[ = c_{\text{top}}(E) \cap e_* \left( \frac{c_{\text{top}}(E'_d) \cap [\overline{M}_{0,0}(X, d)]^{\mathrm{vir}}}{h(h-c)} \right) \]

Note also that \( i_*(1) = i_*(\beta) = c_{\text{top}}(E) \cap [X] \). Now the theorem follows readily. \( \Box \)
