MODULE STRUCTURE ON INVARIANT JACOBIANS

NANHUA XI

Abstract. In this paper we show that Yau’s conjecture on highest weights of invariant Jacobians holds for arbitrary connected semisimple algebraic groups over an algebraically closed field of characteristic 0.

1. Introduction

This work was motivated by a conjecture of Stephen Yau on the set of highest weights of invariant Jacobians by an \( sl(2, \mathbb{C}) \) action, which was proposed in 1985, see 2.2 for a precise statement. The conjecture arose from Yau’s study of singularities, see [2, 5–7].

It was well known that Brieskorn in his talk of ICM1970 established a relation between simple Lie algebras and simple singularities. There is no further generalization to arbitrary singularities. In 1981, Mather and Yau proved that the complex structure of the isolated hypersurface singularity defined by an analytic function \( f \) determines and is determined by its moduli algebra \( A(f) \) which is \( \mathbb{C}[[x_1, \ldots, x_n]]/(f, \frac{\partial f}{\partial x_1}, \ldots, \frac{\partial f}{\partial x_n}) \), see [2]. The algebra \( A(f) \) is a finite-dimensional commutative algebras. Yau defined the Lie algebra \( L(f) \) to be the derivation algebra of \( A(f) \), which are often called Yau algebra now. In the process of proving that \( L(f) \) is a finite-dimensional solvable Lie algebra, Yau made his conjecture nearly 30 years ago. A special case of Yau’s conjecture was proved in [4] and was applied to prove Yau algebras are solvable (see [9]). Yau’s work establishes a connection between the theory of isolated singularities and the theory of solvable Lie algebras. In particular, one can construct deformation of solvable Lie algebras by studying deformation of singularities (see for example [3]).

Yau’s conjecture was proved for the following cases: (a) \( n \leq 5 \), see [8], (b) irreducible action, see [4], (c) some special cases for \( n = 6, 8 \); see [10, 11]. Kempf did some interesting work related to Yau’s conjecture (see [1]), which we will recall in the next section.

In this paper, we will establish several module homomorphisms; see Theorem 3.1 and Theorem 3.3. Combining a result of Kempf, a consequence of one module homomorphism is that Yau’s conjecture on highest weights of invariant Jacobians holds for arbitrary connected semisimple algebraic groups over an algebraically closed field of characteristic 0; see Corollary 3.2 and remark to it. We will also give a direct proof for Yau’s conjecture in Section 4.2.
2. Notations

2.1. Let $G$ be either a group or a Lie algebra, $K$ a field and $\rho$ a representation of $G$ on $V = K^n$. Then $G$ acts on the ring $A = K[x_1, x_2, \ldots, x_n]$ of polynomial functions on $K^n$ and on the ring $R = K(x_1, x_2, \ldots, x_n)$ of rational functions on $K^n$, by abuse of notation, the two representations are denoted by the same letter $\tau$. The subspace $A_d$ of $A$ consisting of homogeneous polynomials of degree $d$ is a $G$-submodule of $A$. For a rational function $f$ in $R$, the Jacobian $J(f)$ is the subspace $R$ spanned by all the partial derivatives $\frac{\partial f}{\partial x_j}$, the $r$th Jacobian $J_r(f)$ is the subspace spanned by all the partial derivatives $\frac{\partial^r f}{\partial x_{i_1} \cdots \partial x_{i_r}}$ of $r$th-order. It is clear that $J_r(f)$ is invariant if $Kf$ is invariant, see [1,8]. (Convention: in this paper invariant means $G$-invariant.)

We shall denote by $S^r(V)$ the $r$-th symmetric power of $V$.

2.2. Yau’s conjecture can be stated as follows: assume that $G = SL_2(\mathbb{C})$ and $V$ is a rational $G$-module, if $J(f)$ is invariant, then the set of highest weights of $J(f)$ is a subset of the set of highest weights of $A_1$.

2.3. Assume that $K$ is an algebraically closed field of characteristic 0 and $G$ is a connected semisimple algebraic group over $K$. Assume that $d$ is an integer greater than 2. Let $f \in A_d$ be such that $J(f)$ is invariant. Kempf showed that if $f = 0$ is projectively smooth or $\rho$ is irreducible, then $f$ is an invariant; see [1]. Kempf also showed in the same paper that if $f$ is homogenous of degree greater than 2 and $J(f)$ is invariant, then there is an invariant homogeneous polynomial $g$ in $A$ with the same degree as of $f$ such that $J(f) = J(g)$.

3. Main results

In this section, we establish several module homomorphisms and show that Yau’s conjecture is true for a connected semisimple algebraic group over an algebraically closed field of characteristic 0 (see Corollary 3.2).

**Theorem 3.1.** Keep the notations in 2.1. Let $e_1, \ldots, e_n$ be the standard basis of $V$ so that $x_i(e_j) = \delta_{ij}$. 

(a) The linear map $A \otimes V \to A$ defined by $f \otimes e_i \to \frac{\partial f}{\partial x_i}$ is a homomorphism of $G$-modules. (Note that $G$ stands for a group or a Lie algebra.)

(b) The linear map $R \otimes V \to R$ defined by $f \otimes e_i \to \frac{\partial f}{\partial x_i}$ is a homomorphism of $G$-modules.

(c) Let $f \in R$. If $Kf$ is a $G$-submodule of $R$, then $J(f)$ is a quotient module of $Kf \otimes V$. In particular, if $f$ is invariant, then $J(f)$ is a quotient module of $V$.

(d) Assume that $f \in R$ is invariant, then $J_r(f)$ is a quotient module of the $r$-th symmetric power $S^r(V)$ of $V$.

**Proof.** Clearly (a) follows from (b). Let $f$ be a rational function in $R$.

(1) Assume that $G$ is a group. We need to show that the map sends $\tau(t)f \otimes \rho(t)(e_i)$ to $\tau(t)\left(\frac{\partial f}{\partial x_i}\right)$ for any $t$ in $G$. Let $\rho(t)(e_i) = \sum_{j=1}^{n} a_{ji}(t)e_j$, then $\tau(t)(x_k) = \sum_{j=1}^{n} a_{kj}(t^{-1})x_j$. 

We first assume that \( f = x_1^{a_1} \cdots x_n^{a_n} \) is a monomial. The linear map sends \( \tau(t) f \otimes \rho(t)(e_i) \) to

\[
\sum_{j=1}^{n} a_{ji}(t) \frac{\partial(\tau(t)f)}{\partial x_j} = \sum_{j=1}^{n} a_{ji}(t) \sum_{k=1}^{n} a_k a_{kj}(t^{-1}) \tau(t)(x_1^{a_1} \cdots x_{k-1}^{a_{k-1}} x_{k}^{a_k-1} x_{k+1}^{a_{k+1}} \cdots x_n^{a_n})
\]

\[
= \sum_{k=1}^{n} a_k \left( \sum_{j=1}^{n} a_{kj}(t^{-1}) a_{ji}(t) \right) \tau(t)(x_1^{a_1} \cdots x_{k-1}^{a_{k-1}} x_{k}^{a_k-1} x_{k+1}^{a_{k+1}} \cdots x_n^{a_n})
\]

\[
= \sum_{k=1}^{n} \delta_{kj} a_k \tau(t)(x_1^{a_1} \cdots x_{k-1}^{a_{k-1}} x_{k}^{a_k-1} x_{k+1}^{a_{k+1}} \cdots x_n^{a_n})
\]

\[
= a_i \tau(t)(x_1^{a_1} \cdots x_{i-1}^{a_{i-1}} x_{i}^{a_i-1} x_{i+1}^{a_{i+1}} \cdots x_n^{a_n})
\]

\[
= \tau(t) \left( \frac{\partial f}{\partial x_i} \right).
\]

Hence, the linear map is a \( G \)-homomorphism from \( A \otimes V \) to \( A \) if \( G \) is a group.

Now assume that \( g, h \) are polynomial functions on \( V \) and \( f = hg^{-1} \). By the above computation, we have

\[
\sum_{j=1}^{n} a_{ji}(t) \frac{\partial(\tau(t)g)}{\partial x_j} = \tau(t) \left( \frac{\partial g}{\partial x_i} \right), \quad \sum_{j=1}^{n} a_{ji}(t) \frac{\partial(\tau(t)h)}{\partial x_j} = \tau(t) \left( \frac{\partial h}{\partial x_i} \right).
\]

Therefore, the linear map sends \( \tau(t)(hg^{-1}) \otimes \rho(t)(e_i) \) to

\[
\sum_{j=1}^{n} a_{ji}(t) \frac{\partial(\tau(t)(hg^{-1}))}{\partial x_j} = \sum_{j=1}^{n} a_{ji}(t) \frac{1}{\tau(t)(g^2)} \left[ \tau(t)(g) \frac{\partial(\tau(t)h)}{\partial x_j} - \tau(t)(h) \frac{\partial(\tau(t)g)}{\partial x_j} \right]
\]

\[
= \frac{1}{\tau(t)(g^2)} \left[ \tau(t)(g) \tau(t) \left( \frac{\partial h}{\partial x_i} \right) - \tau(t)(h) \tau(t) \left( \frac{\partial g}{\partial x_i} \right) \right]
\]

\[
= \tau(t) \left( \frac{\partial (hg^{-1})}{\partial x_i} \right).
\]

Hence, the linear map is a \( G \)-homomorphism from \( R \otimes V \) to \( R \) if \( G \) is a group.

(2) Assume that \( G \) is a Lie algebra. We need to show that the map sends \( \tau(t)f \otimes e_i + f \otimes \rho(t)(e_i) \) to \( \tau(t) \left( \frac{\partial f}{\partial x_i} \right) \) for any \( t \) in \( G \). Let \( \rho(t)(e_i) = \sum_{j=1}^{n} a_{ji} e_j \), then \( \tau(t)(x_j) = -\sum_{k=1}^{n} a_{jk} x_k \).

We first assume that \( f = x_1^{a_1} \cdots x_n^{a_n} \) is a monomial. Set \( b_k = a_k \), if \( k \neq i, j \) and \( b_k = a_k - 1 \) if \( k = i, j \). Noting that

\[
\tau(t)f = \sum_{j=1}^{n} \left[ a_{ji} x_1^{a_1} \cdots x_{j-1}^{a_{j-1}} x_j^{a_j-1} x_{j+1}^{a_{j+1}} \cdots x_n^{a_n} \left( -\sum_{k=1}^{n} a_{jk} x_k \right) \right],
\]
we see that \( \tau(t)f \otimes e_i + f \otimes \rho(t)(e_i) \) is sent to
\[
\sum_{j \neq i}^n \left[ a_j a_i x_1 b_1 x_2 b_2 \cdots x_n b_n \left( -\sum_{k=1}^n a_{jk} x_k \right) \right] \\
+ a_i (a_i - 1) x_1^{a_1} \cdots x_{i-1}^{a_i-1} x_i^{a_i-2} x_{i+1}^{a_{i+1}} \cdots x_n^{a_n} \left( -\sum_{k=1}^n a_{ik} x_k \right)
\]
\[
+ \sum_{j=1}^n a_j (-a_{ji}) x_1^{a_1} \cdots x_{j-1}^{a_{j-1}} x_j^{a_j-1} x_{j+1}^{a_{j+1}} \cdots x_n^{a_n}
\]
\[
+ \sum_{j=1}^n a_j a_{ji} x_1^{a_1} \cdots x_{j-1}^{a_{j-1}} x_j^{a_j-1} x_{j+1}^{a_{j+1}} \cdots x_n^{a_n}
\]
\[
= \sum_{j \neq i}^n \left[ a_j a_i x_1 b_1 x_2 b_2 \cdots x_n b_n \left( -\sum_{k=1}^n a_{jk} x_k \right) \right] \\
+ a_i (a_i - 1) x_1^{a_1} \cdots x_{i-1}^{a_i-1} x_i^{a_i-2} x_{i+1}^{a_{i+1}} \cdots x_n^{a_n} \left( -\sum_{k=1}^n a_{ik} x_k \right)
\]
\[
= \tau(t) \left( \frac{\partial f}{\partial x_i} \right).
\]
So the linear map is a \( G \)-homomorphism of \( G \)-module from \( A \otimes V \) to \( A \) if \( G \) is a Lie algebra.

Now assume that \( g, h \) are polynomial functions on \( V \) and \( f = hg^{-1} \). By the above computation, we have
\[
\frac{\partial (\tau(t)g)}{\partial x_i} + \sum_{j=1}^n a_{ji} \frac{\partial g}{\partial x_j} = \tau(t) \left( \frac{\partial g}{\partial x_i} \right), \quad \frac{\partial (\tau(t)h)}{\partial x_i} + \sum_{j=1}^n a_{ji} \frac{\partial h}{\partial x_j} = \tau(t) \left( \frac{\partial h}{\partial x_i} \right).
\]
Noting that \( \tau(t)(g^{-a}) = -ag^{-a-1}\tau(t)(g) \) for \( a \geq 1 \) and \( \tau(t)(hg^{-1}) = g^{-1}\tau(t)(h) + h\tau(t)(g^{-1}) \), we see that \( \tau(t)(hg^{-1}) \otimes e_i + hg^{-1} \otimes \rho(t)(e_i) \) is sent to
\[
\frac{\partial (g^{-1}\tau(t)(h))}{\partial x_i} - \frac{\partial (g^{-2}h\tau(t)(g))}{\partial x_i} + \sum_{j=1}^n a_{ji} \frac{\partial (g^{-1}h)}{\partial x_j}
\]
\[
= g^{-1} \frac{\partial (\tau(t)(h))}{\partial x_i} - g^{-2} \tau(t)(h) \frac{\partial g}{\partial x_i} + 2g^{-3} h\tau(t)(g) \frac{\partial g}{\partial x_i}
\]
\[
- g^{-2} \tau(t)(g) \frac{\partial h}{\partial x_i} - g^{-2} h \frac{\partial (\tau(t)(g))}{\partial x_i} + \sum_{j=1}^n a_{ji} \left( g^{-1} \frac{\partial h}{\partial x_j} - g^{-2} h \frac{\partial g}{\partial x_j} \right)
\]
\[
= g^{-1} \tau(t) \left( \frac{\partial h}{\partial x_i} \right) - g^{-2} \tau(t)(h) \frac{\partial g}{\partial x_i} + 2g^{-3} h\tau(t)(g) \frac{\partial g}{\partial x_i}
\]
\[
- g^{-2} \tau(t)(g) \frac{\partial h}{\partial x_i} - g^{-2} h\tau(t) \left( \frac{\partial g}{\partial x_i} \right)
\]
\[
= \tau(t) \left( \frac{\partial (hg^{-1})}{\partial x_i} \right).
\]
Hence, the linear map is a \( G \)-homomorphism from \( R \otimes V \) to \( R \) if \( G \) is a Lie algebra.
(c) follows from (b) and (d) follows from (c). The theorem is proved. □

**Corollary 3.2.** Assume that $K$ is an algebraically closed field of characteristic 0 and $G$ is a connected semisimple algebraic group over $K$. If $f \in A$ is homogenous of degree greater than 2 and $J(f)$ is invariant, then $J_r(f)$ is a quotient module of $S^r(V)$.

**Proof.** According [1, Theorem 13], there is an invariant homogenous polynomial $g$ in $A$ with the same degree as of $f$ such that $J(f) = J(g)$, the corollary then follows from Theorem 3.1 (d). □

**Remark.** Since $A_1$ is the dual module of $V$, so that for $G = SL_2(K)$, $V$ is isomorphic $A_1$ as $G$-modules, Yau’s conjecture then follows from Corollary 3.2 for $G = SL_2(\mathbb{C})$ and $r = 1$. Corollary 3.2 shows that Yau’s conjecture holds in a more general setting.

**Theorem 3.3.** Keep the notations in 2.1.

(a) The linear map $A \to A \otimes A$ defined by $f \to \sum_{i=1}^{n} x_i \otimes \frac{\partial f}{\partial x_i}$ is a homomorphism of $G$-modules.

(b) The linear map $R \to A \otimes R$ defined by $f \to \sum_{i=1}^{n} x_i \otimes \frac{\partial f}{\partial x_i}$ is a homomorphism of $G$-modules.

**Proof.** Assume that $f$ is a rational function in $R$.

(1) Let $G$ be a group and $t \in G$. We need to show that the map sends $\tau(t)f$ to $\sum_{i=1}^{n} \tau(t)x_i \otimes \tau(t)\left(\frac{\partial f}{\partial x_i}\right)$. Let $\tau(t)(x_i) = \sum_{j=1}^{n} b_{ji}x_j$.

First we assume that $f = x_1^{a_1} \cdots x_n^{a_n}$ is a monomial. The linear map sends $\tau(t)f$ to

$$\sum_{j=1}^{n} x_j \otimes \frac{\partial(\tau(t)f)}{\partial x_j}$$

$$= \sum_{j=1}^{n} x_j \otimes \sum_{i=1}^{n} a_i b_{ji} \tau(t)(x_1^{a_1} \cdots x_{i-1}^{a_{i-1}} x_i^{a_i-1} x_{i+1}^{a_{i+1}} \cdots x_n^{a_n})$$

$$= \sum_{i=1}^{n} \left[ \sum_{j=1}^{n} b_{ji} x_j \otimes a_i \tau(t)(x_1^{a_1} \cdots x_{i-1}^{a_{i-1}} x_i^{a_i-1} x_{i+1}^{a_{i+1}} \cdots x_n^{a_n}) \right]$$

$$= \sum_{i=1}^{n} \tau(t)x_i \otimes \tau(t)\left(\frac{\partial f}{\partial x_i}\right).$$

Hence, the linear map is a $G$-homomorphism from $A$ to $A \otimes A$ if $G$ is a group.

Now assume that $g, h$ are polynomial functions on $V$ and $f = hg^{-1}$. By the above computation, we have

$$\sum_{i=1}^{n} x_i \otimes \frac{\partial(\tau(t)g)}{\partial x_i} = \sum_{i=1}^{n} \tau(t)x_i \otimes \tau(t)\left(\frac{\partial g}{\partial x_i}\right)$$

$$\sum_{i=1}^{n} x_i \otimes \frac{\partial(\tau(t)h)}{\partial x_i} = \sum_{i=1}^{n} \tau(t)x_i \otimes \tau(t)\left(\frac{\partial h}{\partial x_i}\right).$$
Therefore, the linear map sends $\tau(t)(hg^{-1})$ to

$$
\sum_{i=1}^{n} x_i \otimes \frac{\partial(\tau(t)(hg^{-1})}{\partial x_i}
= \sum_{i=1}^{n} x_i \otimes \left[ \tau(t)(g^{-1}) \frac{\partial(\tau(t)h)}{\partial x_i} - \tau(hg^{-2}) \frac{\partial(\tau(t)g)}{\partial x_i} \right]
= \sum_{i=1}^{n} \tau(t)x_i \otimes \left[ \tau(t)(g^{-1}) \tau(t) \left( \frac{\partial h}{\partial x_i} \right) - \tau(hg^{-2}) \tau(t) \left( \frac{\partial g}{\partial x_i} \right) \right]
= \sum_{i=1}^{n} \tau(t)x_i \otimes \tau(t) \frac{\partial(hg^{-1})}{\partial x_i}.
$$

Hence, the linear map is a $G$-homomorphism from $R$ to $A_1 \otimes R$ if $G$ is a group.

(2) Let $G$ be a Lie algebra. We need show that the map sends $\tau(t)f$ to $\sum_{i=1}^{n}[x_i \otimes \tau(t)(\frac{\partial f}{\partial x_i}) + \tau(t)x_i \otimes \frac{\partial f}{\partial x_i}]$. Let $\tau(t)(x_i) = \sum_{j=1}^{n} b_{ij} x_j$.

First we assume that $f = x_1^{a_1} \cdots x_n^{a_n}$ is a monomial. We have

$$
\tau(t)f = \sum_{j=1}^{n} \left( a_j x_1^{a_1} \cdots x_{j-1}^{a_{j-1}} x_j^{a_j-1} x_{j+1}^{a_{j+1}} \cdots x_n^{a_n} \sum_{k=1}^{n} b_{kj} x_k \right).
$$

Let $b_r = a_r$ if $r \neq i, j$ and $b_r = a_r - 1$ if $r = i, j$. Then the linear map sends $\tau(t)f$ to

$$
\sum_{i=1}^{n} x_i \otimes \frac{\partial(\tau(t)f)}{\partial x_i}
= \sum_{i=1}^{n} x_i \otimes \sum_{j=1}^{n} \left( a_j a_i x_1^{b_1} x_2^{b_2} \cdots x_n^{b_n} \sum_{k=1}^{n} b_{kj} x_k \right)
+ \sum_{i=1}^{n} x_i \otimes a_i (a_i - 1) x_1^{a_1} \cdots x_{i-1}^{a_{i-1}} x_i^{a_i-2} x_{i+1}^{a_{i+1}} \cdots x_n^{a_n} \left( \sum_{k=1}^{n} b_{ki} x_k \right)
+ \sum_{i=1}^{n} x_i \otimes \sum_{j=1}^{n} a_j b_{ij} x_1^{a_1} \cdots x_{j-1}^{a_{j-1}} x_j^{a_j-1} x_{j+1}^{a_{j+1}} \cdots x_n^{a_n}
= \sum_{i=1}^{n} x_i \otimes \tau(t) \left( \frac{\partial f}{\partial x_i} \right)
+ \sum_{j=1}^{n} \left( \sum_{i=1}^{n} b_{ij} x_i \otimes a_j x_1^{a_1} \cdots x_{j-1}^{a_{j-1}} x_j^{a_j-1} x_{j+1}^{a_{j+1}} \cdots x_n^{a_n} \right)
+ \sum_{j=1}^{n} \tau(t)x_j \otimes \frac{\partial f}{\partial x_j}
= \sum_{i=1}^{n} \left[ x_i \otimes \tau(t) \left( \frac{\partial f}{\partial x_i} \right) + \tau(t)x_i \otimes \frac{\partial f}{\partial x_i} \right].
$$

Hence, the linear map is a $G$-homomorphism from $A$ to $A_1 \otimes A$ if $G$ is a Lie algebra.
Now assume that $g, h$ are polynomial functions on $V$ and $f = hg^{-1}$. By the above computation, we have

\[
\sum_{i=1}^{n} x_i \otimes \frac{\partial (\tau(t)g)}{\partial x_i} = \sum_{i=1}^{n} \left[ x_i \otimes \tau(t) \left( \frac{\partial g}{\partial x_i} \right) + \tau(t)x_i \otimes \frac{\partial g}{\partial x_i} \right],
\]

\[
\sum_{i=1}^{n} x_i \otimes \frac{\partial (\tau(t)h)}{\partial x_i} = \sum_{i=1}^{n} \left[ x_i \otimes \tau(t) \left( \frac{\partial h}{\partial x_i} \right) + \tau(t)x_i \otimes \frac{\partial h}{\partial x_i} \right].
\]

Therefore, the linear map sends $\tau(t)(hg^{-1}) = g^{-1} \tau(t)(h) - g^{-2} h \tau(t)(g)$ to

\[
\sum_{i=1}^{n} x_i \otimes \left[ \frac{\partial (g^{-1} \tau(t)h)}{\partial x_i} - \frac{\partial (g^{-2} h \tau(t)g)}{\partial x_i} \right]
\]

\[
= \sum_{i=1}^{n} x_i \otimes \left[ g^{-1} \tau(t) \frac{\partial h}{\partial x_i} - g^{-2} \tau(t) \frac{\partial h}{\partial x_i} - 2g^{-3} h \tau(t) \frac{\partial g}{\partial x_i} - g^{-2} \tau(t) \frac{\partial g}{\partial x_i} - 2g^{-2} h \tau(t) \frac{\partial g}{\partial x_i} \right]
\]

\[
= \sum_{i=1}^{n} x_i \otimes \left[ g^{-1} \tau(t) \left( \frac{\partial h}{\partial x_i} - \frac{\partial g}{\partial x_i} \right) - g^{-2} \tau(t) \left( \frac{\partial h}{\partial x_i} - \frac{\partial g}{\partial x_i} \right) - 2g^{-3} h \tau(t) \left( \frac{\partial g}{\partial x_i} \right) \right]
\]

\[
= \sum_{i=1}^{n} \tau(t)x_i \otimes \left( g^{-1} \frac{\partial h}{\partial x_i} - g^{-2} h \frac{\partial g}{\partial x_i} \right)
\]

\[
= \sum_{i=1}^{n} \left[ x_i \otimes \tau(t) \left( \frac{\partial (hg^{-1})}{\partial x_i} \right) + \tau(t)x_i \otimes \frac{\partial (hg^{-1})}{\partial x_i} \right].
\]

Hence, the linear map is a $G$-homomorphism from $R$ to $A_1 \otimes R$ if $G$ is a Lie algebra. The theorem is proved.

\[\square\]

**Corollary 3.4.** Keep the notations in 2.1.

(a) If $f \in R$ is invariant, then $\sum_{i=1}^{n} x_i \otimes \frac{\partial f}{\partial x_i}$ is invariant in $A_1 \otimes R$.

(b) If $d$ is a positive integer and $d$ is invertible in $K$, then $A_d$ is a direct summand of $A_1 \otimes A_{d-1}$.

**Proof.** (a) is clear from Theorem 3.3 (b). We have a natural $G$-homomorphism $\psi : A_1 \otimes R \to R$, $x_i \otimes f \mapsto x_i f$. Let $\varphi$ be the map in Theorem 3.3 (b) and $f \in A_d$. Then $\psi \varphi(f) = df$. Since $d$ is invertible in $K$, we have $A_1 \otimes A_{d-1} \simeq A_d \oplus \ker \psi'$, here $\psi'$ is the restriction of $\psi$ to $A_1 \otimes A_{d-1}$. The corollary is proved.

\[\square\]

**3.5. Question** Keep the notations in 2.1. Let $f \in R$ be such that $J(f)$ is invariant. (a) describe the module structure of $J(f)$, (b) does there exist $g \in R$ such that $Kg$ is invariant and $J(g) = J(f)$? (c) describe the set $\{g \in R \mid J(g) = J(f)\}$. 

4. A direct proof for Yau’s conjecture

4.1. We use the setup of [8] (see also [4, 10, 11]) to give a direct proof for Yau’s conjecture, see part (c) of Proposition 4.2. Let $K$ be an algebraically closed field of characteristic 0 and $A$ be as in 2.1. Let $H, X, Y$ be the standard basis of $sl_2(K)$ so we have $[X, Y] = H, [H, X] = 2X, [H, Y] = -2Y$.

Let $l_1, \ldots, l_r$ be positive integers such that their sum is $n$. For $1 \leq i \leq r$, define

$$H_i = (l_i - 1)x_{l_1 + \cdots + l_i - 1 + 1} \frac{\partial}{\partial x_{l_1 + \cdots + l_i - 1 + 1}}$$

$$+ \cdots + (l_i - 2j + 1)x_{l_1 + \cdots + l_i - 1 + j} \frac{\partial}{\partial x_{l_1 + \cdots + l_i + j}}$$

$$+ \cdots + (-l_i + 1)x_{l_1 + \cdots + l_i} \frac{\partial}{\partial x_{l_1 + \cdots + l_i}},$$

$$X_i = (l_i - 1)x_{l_1 + \cdots + l_i - 1 + 1} \frac{\partial}{\partial x_{l_1 + \cdots + l_i - 1 + 2}}$$

$$+ \cdots + j(l_i - j)x_{l_1 + \cdots + l_i - 1 + j} \frac{\partial}{\partial x_{l_1 + \cdots + l_i + j + 1}}$$

$$+ \cdots + (l_i - 1)x_{l_1 + \cdots + l_i - 1} \frac{\partial}{\partial x_{l_1 + \cdots + l_i}},$$

$$Y_i = x_{l_1 + \cdots + l_i + 2} \frac{\partial}{\partial x_{l_1 + \cdots + l_i - 1 + 1}}$$

$$+ \cdots + x_{l_1 + \cdots + l_i + j} \frac{\partial}{\partial x_{l_1 + \cdots + l_i - 1 + j - 1}}$$

$$+ \cdots + x_{l_1 + \cdots + l_i} \frac{\partial}{\partial x_{l_1 + \cdots + l_i - 1}}.$$  

Then the map $H \rightarrow H_1 + \cdots + H_r, X \rightarrow X_1 + \cdots + X_r$ and $Y \rightarrow Y_1 + \cdots + Y_r$ defines an action of $sl_2(K)$ on $A$. Under this action, $x_{l_1 + \cdots + l_i + j}$ is a vector of weight $l_i - 2j + 1$, and the elements $x_{l_1 + \cdots + l_i + 1}, x_{l_1 + \cdots + l_i + 2}, \ldots, x_{l_1 + \cdots + l_i - l_i + 1}, x_{l_1 + \cdots + l_i}$ span an irreducible submodule of $A$ of dimension $l_i$.

**Proposition 4.1.**  
(a) The linear map $A \otimes A_1 \rightarrow A, f \otimes x_i \rightarrow (-1)^i \frac{\partial f}{\partial x_i'}$ is a homomorphism of $sl_2(K)$-modules, $i'$ is determined by the following conditions:  
(1) $x_{i'}$ is in the submodule generated by $x_i$ and (2) the weight of $x_{i'}$ is opposite to that of $x_i$, i.e., $i' = l_1 + \cdots + l_i - 1 + l_i - j + 1$ if $i = l_1 + \cdots + l_i + 1 + j$ for $1 \leq j \leq l_i$.

(b) If $f \in A$ is invariant, then $J(f)$ is a quotient module of $A_1$.

(c) Let $f \in A_d$ and $d \geq 3$. If $J(f)$ is invariant, then $J(f)$ is a quotient module of $A_1$. In particular, in this case the set of highest weights of $J(f)$ is a subset of the set of highest weights of $A_1$.

**Proof.** Part (a) can be checked by a direct calculation. Part (b) follows from (a). Now we prove part (c). By [1, Theorem 13], there exists $g \in A_d$ such that $g$ is invariant and $J(g) = J(f)$. Thus, (c) follows from (b). The proposition is proved.

**Remark.** It is easy to see that the homomorphism in Proposition 4.2 (a) can be uniquely extended to homomorphism $R \otimes A_1 \rightarrow R$. 

Acknowledgments

I thank Stephen Yau for talking me his interesting conjecture during a lunch and for explaining me the background of his conjecture. Supported in part by the President Foundation of the AMSS, Chinese Academy of Sciences.
