

Formally integrable complex structures on higher dimensional knot spaces

DOMENICO FIORENZA AND HÔNG VÂN LÊ

Let S be a compact oriented finite dimensional manifold and M a finite dimensional Riemannian manifold, let $\text{Imm}_f(S, M)$ the space of all free immersions $\varphi : S \rightarrow M$ and let $B_{i,f}^+(S, M)$ the quotient space $\text{Imm}_f(S, M)/\text{Diff}^+(S)$, where $\text{Diff}^+(S)$ denotes the group of orientation preserving diffeomorphisms of S . In this paper we prove that if M admits a parallel r -fold vector cross product $\chi \in \Omega^r(M, TM)$ and $\dim S = r - 1$ then $B_{i,f}^+(S, M)$ is a formally Kähler manifold. This generalizes Brylinski's, LeBrun's and Verbitsky's results for the case that S is a codimension 2 submanifold in M , and $S = S^1$ or M is a torsion-free G_2 -manifold respectively.

1. Introduction

Let (M, g) be a finite dimensional Riemannian manifold with a r -fold vector cross product (VCP for short) $\chi \in \Omega^r(M, TM)$. By definition, this means that χ satisfies the following properties

$$\begin{aligned}\langle \chi(v_1, \dots, v_r), v_i \rangle &= 0 \text{ for } 1 \leq i \leq r, \\ \langle \chi(v_1, \dots, v_r), \chi(v_1, \dots, v_r) \rangle &= \|v_1 \wedge \dots \wedge v_r\|^2\end{aligned}$$

where $\langle \cdot, \cdot \rangle$ denotes the inner product defined by g and $\|\cdot\|$ is the induced metric on $\Lambda^r TM$. For a VCP $\chi \in \Omega^r(M, TM)$ we associate the VCP-form $\varphi_\chi \in \Omega^{r+1}(M)$ as follows [LL2007, p. 143]

$$(1.1) \quad \varphi_\chi(v_1, \dots, v_{r+1}) = \langle \chi(v_1, \dots, v_r), v_{r+1} \rangle.$$

The notion of a VCP structure on a manifold was introduced by Gray [BG1967], [Gray1969]. In [BG1967] Brown and Gray classified linear VCPs

Research of HVL was supported by GAČR-project 18-00496S and RVO: 67985840.

on an m -dimensional real vector space V^m with positive definite inner product g . Their results can be summarized as follows:

(1) A 1-fold VCP on V^m exists iff $m = 2n$. It is defined uniquely by its associated VCP-form which is a Kähler form on $V^{2n} \cong V^n \otimes_{\mathbb{R}} \mathbb{C}$.

(2) A $(m - 1)$ -fold VCP on V^m is defined uniquely by its associated VCP-form which is the volume form on (V^m, g) .

(3) A 2-fold VCP exists on V^m iff $m = 7$ and it is defined uniquely by its associated VCP-form, which is the associative 3-form on \mathbb{R}^7 , whose stabilizer is the exceptional Lie group G_2 .

(4) A 3-fold VCP exists on V^m iff $m = 8$ and it is defined uniquely by its associated VCP-form, which is the Cayley 4-form on \mathbb{R}^8 , whose stabilizer is the Lie group $\text{Spin}(7)$.

It follows from Brown-Gray's classification that a Riemannian manifold (M^m, g) admits a r -fold VCP iff either (1) $r = 1$, $m = 2n$ and (M, g) is an almost Hermitian manifold and the associated VCP-form is the fundamental 2-form of the almost Hermitian manifold (M, g) , (2) $r = m - 1$ and (M^m, g) is an orientable Riemannian manifold, (3) $r = 2$, $m = 7$ and (M^7, g) admits an associative 3-form φ^3 , (4) $r = 3$, $m = 8$ and (M^8, g) admits a Cayley 4-form. Hence, a Riemannian manifold (M, g) can be endowed with a parallel r -fold VCP iff either (M^m, g) is an orientable Riemannian manifold and $r = m - 1$; or $m = 2n$, (M^{2n}, g) is a Kähler manifold and $r = 1$; or $m = 7$ and (M^7, g) is a torsion-free G_2 -manifold and $r = 2$; or $m = 8$ and (M^8, g) is a torsion-free $\text{Spin}(7)$ -manifold and $r = 3$. Once more, this result singles out Kähler manifolds, torsion-free G_2 -and $\text{Spin}(7)$ -manifolds as important classes of Riemannian manifolds with special holonomy [Joyce2000]. Not unrelatedly, these classes play a prominent role in calibrated geometry, string theory and M -theory [Joyce2007].

In [LL2007], motivated by Brylinsky's results on the loop spaces of Riemannian 3-manifolds [Brylinsky2008], Lee and Leung initiated the study of moduli spaces $B_e^+(S, M)$ of unparametrized embedded oriented submanifolds in a finite dimensional Riemannian manifold (M^m, g) , diffeomorphic to a closed oriented manifold S , assuming that (M^m, g) admits an r -fold VCP χ and $\dim S = r - 1$. In particular, they proved that if the associated VCP-form φ_χ is closed then φ_χ induces a weak symplectic form on $B_e^+(S, M)$, which is compatible with the weak L_2 -metric on $B_e^+(S, M)$, thus defining an almost Kähler structure. Their result partially extends Brylinsky's theorem for $B_e^+(S^1, M^3)$ and LeBrun's extension to the case $B_e^+(S, M)$ when $\text{codim } S = 2$ [LeBrun1993], stating that if $\text{codim } S = 2$ then the induced weak symplectic form on $B_e^+(S, M)$ is formally Kähler, i.e., it is such that the associated almost complex structure has vanishing Nijenhuis tensor. Few

years after Lee-Leung's work, Verbitsky proved that also the associated almost complex structure J on $B_e^+(S^1, M^7)$ has vanishing Nijenhuis tensor if the associated VCP-form φ^3 is parallel and therefore M^7 is a torsion-free G_2 -manifold [Verbitsky2010]. Almost at the same time, Henrich gave a new proof of Brylinsky's result by showing that J is parallel with respect to the Levi-Civita connection of the L_2 -metric.

Remark 1.1. The formal integrability of the complex structure J on $B_{i,f}^+(S, M)$ does not imply its strong integrability, since the Newlander-Nirenberg theorem does not hold for infinite dimensional manifolds [Lempert1993]. Namely, in the infinite dimensional case if the the Nijenhuis tensor N_J of a complex structure J vanishes, then one still has plenty of local holomorphic functions, but this does not suffice to construct charts with values in an infinite-dimensional Banach or Fréchet space. To overcome this difficulty, in [Lempert1993] Lempert introduced the intermediate notion of weak integrability of an almost complex structure and proved that the almost complex structure on the loop space $B_{i,f}^+(S^1, M^3)$ is weakly integrable. Since weak integrability implies formal integrability, Lempert's result provides in particular a refinement of Brylinsky's proof of the formal integrability of the almost complex structure J on the space $B_{i,f}^+(S^1, M^3)$.

Remark 1.2. Lempert's proof of the weak integrability of the almost complex structure J on $B_{i,f}^+(S^1, M^3)$ uses the twistor construction of a CR 5-manifold over a 3-manifold M^3 proposed by LeBrun in [LeBrun1984]. This twistor construction has been generalized further by LeBrun and Verbitsky to $B_{i,f}^+(S, M)$ in the case that $\text{codim } S = 2$ and the case $\text{dim } S = 1$ & $\text{dim } M = 7$, respectively. Brylinski's original proof of the formal integrability of the almost complex structure J on $B_{i,f}^+(S^1, M^3)$ uses instead an ingenious computation of the Nijenhuis tensor of J .

In this paper we show how Henrich's result admits a natural generalization, allowing us to extend Brylinski's and Verbitsky's results to all cases of Riemannian manifolds (M, g) with parallel VCPs. In particular, this provides a new proof of Verbitsky's result as well as a new proof of LeBrun's result. Also in the case of $B_e^+(S^1, M^3)$ our proof simplifies Henrich's original argument, as we show that consideration on the parallelism of the almost complex structure J with respect to a torsion-free affine connection ∇^\perp alone already allows us to conclude that J is formally integrable. One can then derive from this that J is actually also parallel with respect to the Levi-Civita

connection on $B_e^+(S^1, M^3)$ and more generally, as we show, with respect to any torsion-free connection of $B_e^+(S, M)$ under consideration.

We denote by $\text{Diff}^+(S)$ the group of orientation preserving diffeomorphisms of S and by $\text{Imm}_f(S, M)$ the set of all smooth free immersions $\iota: S \rightarrow M$, i.e., smooth immersions ι such that the stabilizer subgroup of ι in $\text{Diff}^+(S)$ is trivial. For instance, if $\iota: S \rightarrow M$ is a somewhere injective immersion, i.e. there exists $x_0 \in S$ such that $\iota^{-1}(\iota(x_0)) = x_0$, then $\iota \in \text{Imm}_f(S, M)$ [CMM1991, Lemma 1.4]. We will denote by $B_{i,f}^+(S, M)$ the quotient $\text{Imm}_f(S, M)/\text{Diff}^+(S)$. Note that if S is connected, $\text{Diff}^+(S)$ is an index two subgroup of the group $\text{Diff}(S)$ of all diffeomorphisms of S , and therefore $B_{i,f}^+(S, M)$ is a double covering of $B_{i,f}(S, M) := \text{Imm}_f(S, M)/\text{Diff}(S)$. As a side remark we notice that this latter quotient is what is called a *shape space* in computer vision community [BBM2013], [Michor2016].

Having introduced this notation, we can state our

Theorem 1.3 (Main Theorem). *Assume that a Riemannian manifold (M, g) admits a parallel r -fold VCP $\chi \in \Omega^r(M, TM)$. Let S be a closed oriented $(r - 1)$ -dimensional manifold. Then the space $B_{i,f}^+(S, M)$ has a structure of a formally Kähler manifold $(B_{i,f}^+(S, M), J, L_2(g), \omega^2)$ where J is an almost complex structure with vanishing Nijenhuis tensor, $L_2(g)$ is the weak L_2 -metric, and ω^2 is the associated closed weak symplectic 2-form. Furthermore J is parallel w.r.t. to the Levi-Civita connection ∇^{LC} of the weak metric $L_2(g)$.*

Notation and conventions. Through the whole paper S will always be a closed (i.e., compact without boundary) oriented finite dimensional manifold, M a finite dimensional manifold and (M, g) a finite dimensional Riemannian manifold, $\mathfrak{M}, \mathfrak{N}$ smooth manifolds modeled on convenient vector spaces, $\mathfrak{X}(\mathfrak{M})$ the space of smooth (kinematic) vector fields on \mathfrak{M} . For a smooth vector bundle E over a smooth manifold \mathfrak{M} we denote by $\Gamma(E)$ the space of all smooth sections of E . For smooth manifolds \mathfrak{M} and \mathfrak{N} we denote by $C^\infty(\mathfrak{M}, \mathfrak{N})$ the space of all smooth mappings from \mathfrak{M} to \mathfrak{N} . If $\mathfrak{N} = \mathbb{R}$ we abbreviate $C^\infty(\mathfrak{M}, \mathbb{R})$ as $C^\infty(\mathfrak{M})$. For an Euclidean vector bundle $E \rightarrow M$ with a fiberwise metric h and any $u, v \in \Gamma(E)$ we denote by $h(u, v)$ the smooth function on M defined by $h(u, v)(x) := h(u(x), v(x))$ for all $x \in M$.

The paper is organized as follows. In the second section we collect some known results on geometry of the space $B_{i,f}^+(S, M)$ endowed with the weak L_2 -metric. Then we prove one of our main technical results (Lemma 2.8), which is needed for our establishing the explicit formula of the Levi-Civita connection of the L_2 -metric (Theorem 2.10) as well as for the proof of our

Main Theorem. In the last section first we recall Lee-Leung's construction of the almost complex structure on $B_{i,j}^+(S, M)$. Then we give a proof of the Main Theorem.

2. Riemannian geometry of the space $B_{i,f}^+(S, M)$

In this section, first we fix necessary notation and recall some known results on the Fréchet manifold structure of the moduli space $B_{i,f}^+(S, M)$. Then we give an explicit formula for the Levi-Civita connection of the weak L_2 -metric on $B_{i,f}^+(S, M)$ (Theorem 2.10), generalizing to an arbitrary oriented submanifold S results by Henrich for the cases $\dim S = 1$ and $\text{codim } S = 1$ [Henrich2009, Theorem 3.1, p. 25, Theorem 5.21, p. 48]. The proof consists in showing that Henrich's connection ∇^\perp on the space $\text{Imm}_f(S, M)$ [Henrich2009, Definition 5.2, p. 41] is torsion-free independently of the dimension of S . In [Henrich2009] a complete proof of the torsion-freeness of ∇^\perp is only given for the case $\dim S = 1$ [Henrich2009, Lemma 2.17, p. 19], but this proof is supposedly immediately generalized/adapted to the general case (e.g., in [Henrich2009, Definition 5.2, p. 41] the connection ∇^\perp is declared to be torsion-free without the need of a proof). Our proof of the torsion-freeness of ∇^\perp uses Lemma 2.8, which is possibly of independent interest and is employed further in the proof of the Main Theorem.

2.1. The smooth structure on $B_{i,f}^+(S, M)$

The space $B_{i,f}(S, M)$ has been considered by Cervera-Mascaró-Michor in [CMM1991], see also [KM1997, 44.2, p. 476] without the assumption that S is a closed oriented manifold and in [MM2005] with the assumption that S is closed. They observed that the space $\text{Imm}_f(S, M)$ is an open invariant subset in the space $C^\infty(S, M)$ of all smooth maps from S to M endowed with compact-open topology and the right action of $\text{Diff}(S)$. If S is a closed submanifold then any immersion $\iota : S \rightarrow M$ is proper. In this case, the results from the above mentioned papers imply the following statements (1)–(6).

(1) $\text{Imm}_f(S, M)$ can be naturally endowed with the structure of an infinite dimensional smooth manifold modeled on the Fréchet space of smooth sections $\Gamma(\iota^*TM)$ along a smooth immersion $\iota : S \rightarrow M$, see e.g. [KM1997, Theorem 42.1, p. 439].

(2) $\text{Imm}_f(S, M)$ is the total space of a smooth principal fiber bundle $\pi : \text{Imm}_f(S, M) \rightarrow B_{i,f}(S, M)$ whose fiber is $\text{Diff}(S)$, and hence $\text{Imm}_f(S, M)$ is also the total space of a smooth principal fiber bundle $\pi^+ : \text{Imm}_f(S, M) \rightarrow B_{i,f}^+(S, M)$ whose fiber is $\text{Diff}^+(S)$.

(3) $B_{i,f}(S, M)$ and $B_{i,f}^+(S, M)$ are Hausdorff spaces in the quotient topology.

(4) For an immersion $\iota : S \rightarrow M$ let $N_\iota S$ be the normal bundle ι^*TM/TS , whose fiber at $s \in S$ can be identified with the orthogonal complement $T_{\iota(s)}\iota(S)^\perp$ of $T_{\iota(s)}\iota(S)$ in $T_{\iota(s)}M$ if M is a Riemannian manifold. Then $B_{i,f}^+(S, M)$ inherits the structure of a smooth Fréchet manifold locally modeled on the Fréchet space $\Gamma(N_\iota S)$ of smooth sections of $N_\iota S$, which is identified with the kinematic tangent space $T_{[\iota]}B_{i,f}^+(S, M)$, where $[\iota] := \pi^+(\iota)$.

(5) The kinematic tangent bundle $TB_{i,f}^+(S, M)$ has the structure of a smooth vector bundle over $B_{i,f}^+(S, M)$. The Lie bracket of two kinematic vector fields, i.e., of two smooth sections of $TB_{i,f}^+(S, M)$, is well-defined [KM1997, Theorem 32.8, p. 327].

(6) Let $E \rightarrow B_{i,f}^+(S, M)$ be a smooth vector bundle, whose fiber F is a convenient vector space, e.g., $F = \mathbb{R}^n$. Then we denote by

$$L_{alt}^k(TB_{i,f}^+(S, M), E)$$

the smooth bundle over $B_{i,f}^+(S, M)$ whose fiber over $[\iota] \in B_{i,f}^+(S, M)$ consists of all alternating bounded k -linear maps from $T_{[\iota]}B_{i,f}^+(S, M) \times \cdots \times k \text{ times} \times T_{[\iota]}B_{i,f}^+(S, M)$ to $E_{[\iota]}$. We set

$$\Omega^k(B_{i,f}^+(S, M), E) := \Gamma(L_{alt}^k(TB_{i,f}^+(S, M), E))$$

and call it the space of differential forms on $B_{i,f}^+(S, M)$ with values in E [KM1997, §33.22, p. 352]. If $E = B_{i,f}^+(S, M) \times \mathbb{R}$ is the trivial vector bundle with fiber \mathbb{R} over $B_{i,f}^+(S, M)$ then we abbreviate $\Omega^k(B_{i,f}^+(S, M), E)$ as $\Omega^k(B_{i,f}^+(S, M))$.

From now on we shall omit the adjective “kinematic” before “tangent vector (field)”.

Example 2.1. (cf. [LL2007, Vizman2011]) Let $\varphi \in \Omega^k(M)$ and $\dim S = r$. Denote by $p_2 : S \times \text{Imm}_f(S, M) \rightarrow \text{Imm}_f(S, M)$ the projection onto the second factor. Since the evaluation map

$$\begin{aligned} ev : S \times \text{Imm}_f(S, M) &\rightarrow M \\ (s, \iota) &\mapsto \iota(s) \end{aligned}$$

is smooth [KM1997, Corollary 3.1.3(1), p. 31], for any $\varphi \in \Omega^k(M)$ we have $ev^*(\varphi) \in \Omega^k(S \times \text{Imm}_f(S, M))$. Next, using the integration over fiber, which is a differential version of the slant map, we can push $ev^*(\varphi)$ to a form

$(p_2)_*(ev)^*(\varphi) \in \Omega^{k-r}(\text{Imm}_f(S, M))$. It is not hard to see that $(p_2)_*(ev)^*(\varphi) = (\pi^+)^*(\varphi_B)$ where $\varphi_B \in \Omega^{k-r}(B_{i,f}^+(S, M))$ is defined by

$$(2.1) \quad \varphi_B(X_1, \dots, X_{k-r}) := \int_S i_{X_1} \cdots i_{X_{k-r}} \varphi|_S,$$

for $X_1, \dots, X_{k-r} \in \Gamma(N_\iota S)$ where $\varphi|_S \in \Gamma(S, \wedge^r \iota^* TM^*)$ is the restriction of φ to S . If $d\varphi = 0$ then $d(p_2)_*(ev)^*(\varphi) = 0$ and therefore $d\varphi_B = 0$. The form φ_B is called the *transgression* of φ .

Example 2.2. (cf. [LL2007, Vizman2011]) Let $\varphi \in \Omega^k(M, TM)$ and let $\dim S = r$. For any immersion $\iota: S \rightarrow M$, let vol_{ι^*g} be the volume form of S associated with the induced metric ι^*g , and let $\overrightarrow{T_s S} \iota$ denote the unit r -vector of $T_s S$ with respect to this volum form. Let $\Pi: T_{\iota(s)} M \rightarrow N_{\iota(s)} S$ be the natural projection. Then we define the form $\varphi_B \in \Omega^{k-r}(B_{i,f}^+(S, M), TB_{i,f}^+(S, M))$ by

$$(2.2) \quad \varphi_B(X_1, \dots, X_{k-r})(s) := \Pi \left(i_{X_1} \cdots i_{X_{k-r}} (i_{\overrightarrow{T_s S} \iota} \varphi|_S) \right)$$

for $X_1, \dots, X_{k-r} \in \Gamma(N_\iota S)$. The form φ_B is called the *transgression* of φ defined by the induced volume form on S .

2.2. The L_2 -Riemannian metric and its Levi-Civita connection on $B_{i,f}^+(S, M)$

In this subsection we assume that (M, g) is a Riemannian manifold. It is known that the space $B_{i,f}^+(S, M)$ is endowed with the weak L_2 - Riemannian metric defined as follows

$$(2.3) \quad \langle u, v \rangle_{[i]} = \int_S g(u, v) \text{vol}_{\iota^*g},$$

where $u, v \in \Gamma(N_\iota S) = T_{[i]} B_{i,f}^+(S, M)$. The RHS of (2.3) extends naturally to a L_2 -metric on the space $\text{Imm}_f(S, M)$, which is invariant under the action of $\text{Diff}^+(S)$ and therefore it descends to the L_2 -metric on $B_{i,f}^+(S, M)$ making the projection $\pi^+: \text{Imm}_f(S, M) \rightarrow B_{i,f}^+(S, M)$ a Riemannian submersion. Kainz proved the existence of the Levi-Civita connection for the L_2 -metric on the space $\text{Imm}_f(S, M)$ [Kainz1984, Theorem 2.2]. Since the L_2 -metric on $\text{Imm}_f(S, M)$ is $\text{Diff}^+(S)$ -invariant, the associated Levi-Civita connection is also $\text{Diff}^+(S)$ -invariant. A formula for the Levi-Civita connection on $B_{i,f}^+(S, M)$ has been given by Michor and Mumford via the equation

for geodesics on $B_{i,f}^+(S, M)$ [MM2005, §4.2] and explicitly by Henrich in his PhD Thesis for the case $\dim S = 1$ or $\text{codim } S = 1$ [Henrich2009, Theorem 3.1, Theorem 5.21]. In the remaining part of this subsection we shall generalize Henrich’s formula for an arbitrary closed oriented manifold S .

First we recall the notion of an *affine connection* and its associated *covariant differentiation* on a smooth possibly infinite dimensional manifold \mathfrak{M} modelled on a convenient vector space, following [KM1997], [MMM2013], and [Kainz1984]. Denote by $\mathfrak{X}(\mathfrak{M})$ the space of smooth vector fields on \mathfrak{M} .

Definition 2.3. An affine connection on a smooth manifold \mathfrak{M} is a smooth mapping

$$\nabla : \mathfrak{X}(\mathfrak{M}) \times \mathfrak{X}(\mathfrak{M}) \rightarrow \mathfrak{X}(\mathfrak{M})$$

which is a derivation on the second argument and $C^\infty(\mathfrak{M})$ -linear on the first argument. In other words, re-denoting $\nabla(X, Y)$ as $\nabla_X(Y)$, we have

$$(2.4) \quad \nabla_X(Y + Z) = \nabla_X(Y) + \nabla_X(Z)$$

$$(2.5) \quad \nabla_X(fY) = f\nabla_X(Y) + (Xf)Y$$

$$(2.6) \quad \nabla_{fX+gY}(Z) = f\nabla_X Z + g\nabla_Y Z$$

for all $X, Y, Z \in \mathfrak{X}(\mathfrak{M})$ and $f, g \in C^\infty(\mathfrak{M})$. The operator ∇_X is called a *covariant differentiation* w.r.t. X . If the manifold \mathfrak{M} is equipped with a Riemannian metric

$$\langle , \rangle : \mathfrak{X}(\mathfrak{M}) \times \mathfrak{X}(\mathfrak{M}) \rightarrow C^\infty(\mathfrak{M}),$$

then the covariant derivation is called *Levi-Civita*, if it respects the metric and it is torsion-free, i.e.,

$$(2.7) \quad X\langle Y, Z \rangle = \langle \nabla_X Y, Z \rangle + \langle Y, \nabla_X Z \rangle$$

$$(2.8) \quad T^\nabla(X, Y) := \nabla_X Y - \nabla_Y X - [X, Y] = 0.$$

As in the finite dimensional case, the above conditions determine ∇ uniquely, so that, when it exists we talk of *the Levi-Civita connection*.

Remark 2.4. It is not hard to see that the above definition of an affine connection on \mathfrak{M} is equivalent to the definition of an affine connection via a smooth projection $K : T^2\mathfrak{M} \rightarrow T\mathfrak{M}$ [KM1997, Definition 37.2, p. 376].

Furthermore, the notions of an affine connection and of the associated covariant differentiation on \mathfrak{M} are particular cases of those of a linear connection on a smooth vector bundle E over \mathfrak{M} and of its associated covariant differentiation $\nabla : \mathfrak{X}(\mathfrak{M}) \times \Gamma(E) \rightarrow \Gamma(E)$ [KM1997, 37.27, 37.28, p. 397].

Remark 2.5. As $(X, Y) \mapsto \nabla_X Y$ is $C^\infty(\mathfrak{M})$ -linear in the first variable, the datum of a covariant derivative ∇ is equivalent to the datum of all the derivatives

$$\nabla_u : \mathfrak{X}(\mathfrak{M}) \rightarrow T_p \mathfrak{M}$$

with $u \in T_p \mathfrak{M}$ ranging in the tangent space of \mathfrak{M} at p , with p varying over the whole of \mathfrak{M} .

Remark 2.6. The torsion of an affine connection is a tensor, i.e., the value $T^\nabla(X, Y)_p$ of the vector field $T^\nabla(X, Y)$ at the point p of \mathfrak{M} only depends on the values X_p and Y_p of X and Y at p . In other words, one has a well defined bilinear map $u \otimes v \mapsto T_p^\nabla(u, v)$ defined by

$$T_p^\nabla(u, v) = T^\nabla(X, Y)_p$$

where X and Y are arbitrary extensions of the tangent vectors u and v at the point p , respectively, to tangent vector fields on a 2-dimensional surface in \mathfrak{M} .

Next, following [MM2005], cf.[Henrich2009], we shall express the Levi-Civita connection ∇^{LC} on $B_{i,f}^+(S, M)$ w.r.t. the L_2 -metric as a sum of a torsion-free affine connection ∇^\perp on $B_{i,f}^+(S, M)$ and a symmetric tensor \mathfrak{B} . By Remark 2.5, to define ∇^\perp it suffices to define ∇_u^\perp for every tangent vector u in $T_{[\iota]} B_{i,f}^+(S, M)$. Let $\gamma: \mathbb{R} \rightarrow \text{Imm}_f(S, M)$ be a path of free immersions with $\gamma(0) = \iota$ whose velocity vector $\dot{\gamma}|_{t=0}$ at $t = 0$ is a lift/a representative of the tangent vector u in $\Gamma(\iota^* TM)$. For all $k \in \mathbb{N}$ we have isomorphisms

$$(2.9) \quad C^\infty(\mathbb{R}^k, C^\infty(S, M)) = C^\infty(\mathbb{R}^k \times S, M).$$

By means of this for $k = 1$, we identify γ with a map, which we will denote by the same symbol, $\gamma: \mathbb{R} \times S \rightarrow M$, [KM1997, Corollary 3.13, p. 31]. At any point s of S , $\gamma(\cdot, s)$ defines a curve in M whose velocity vector $u(s)$ at $t = 0$ is a vector in $T_{\gamma(0,s)} M$. For any vector field X on $B_{i,f}^+(S, M)$, and for any fixed t , the vector $X_{[\gamma(t)]}$ can be identified with a section of the normal bundle $N_{\gamma(t)} S$. By identifying $N_{\gamma(t)} S$ with a subbundle of the tangent bundle $(\gamma(t))^* TM$, e.g., by means of the Riemannian metric as in Subsection 2.1 (4), we can think of $X_{[\gamma]} := X \circ \gamma$ as a section of $\gamma^* TM$. The pullback of the Levi-Civita connection on TM gives a connection $\gamma^*(\nabla^{LC;M})$ on $\gamma^* TM$

and we can define

$$(2.10) \quad (\nabla_u^\perp X) := (\gamma^*(\nabla^{LC;M})_{\frac{\partial}{\partial t}} X_{[\gamma]}|_{t=0})^\perp,$$

where on the right hand side $(-)^\perp$ denotes its projection on the normal bundle $N_{[\iota]}S$.

Proposition 2.7. (cf. [Henrich2009, Lemma 2.17]) *The formula (2.10) defines a torsion-free connection on $B_{i,f}^+(S, M)$.*

Proof. One immediately sees that (2.10) defines an affine connection, so we are only left with showing that the torsion $T^\perp(u, v)$ of ∇^\perp vanishes for any $u, v \in T_{[\iota]}B_{i,f}^+(S, M) = N_\iota S$. To do this we shall use the following argument, which shall be utilized several times in our paper.

We consider a deformation

$$\gamma : (-\varepsilon, \varepsilon) \times (-\varepsilon, \varepsilon) \times S \rightarrow M, \quad (x, y, s) \mapsto \gamma(x, y, s),$$

such that for all $s \in S$,

$$\gamma(0, 0, s) = \iota(s), \quad \left. \frac{d\gamma}{dx} \right|_{(0,0,s)} = u(s), \quad \text{and} \quad \left. \frac{d\gamma}{dy} \right|_{(0,0,s)} = v(s).$$

More explicitly we set

$$(2.11) \quad \gamma(x, y, s) := \text{Exp}_{\iota(s)}(x \cdot u(s) + y \cdot v(s)),$$

where $\text{Exp}_{\iota(s)} : T_{\iota(s)}M \rightarrow M$ is the exponential map for the Riemannian manifold M at the point $\iota(s)$. This deformation extends the vectors $u, v \in T_{[\iota]}B_{i,f}^+(S, M) = N_\iota S$ to vector fields, that we denote by X and Y , along the image of $\gamma((-\varepsilon, \varepsilon) \times (-\varepsilon, \varepsilon))$ in $\text{Imm}_f(S, M)$ via the isomorphism (2.9), i.e., the vector field X is defined by

$$(2.12) \quad X_{\gamma(x,y)}(s) = (d\text{Exp}_{\iota(s)})|_{x u(s) + y v(s)}(u(s))$$

and similarly for Y . The projection $\pi^+ : \text{Imm}_f(S, M) \rightarrow B_{i,f}^+(S, M)$ maps X, Y to vector fields $X^{\text{ver}}, Y^{\text{ver}}$ along the image of $\pi^+ \circ \gamma((-\varepsilon, \varepsilon) \times (-\varepsilon, \varepsilon))$. By definition we can identify $X^{\text{ver}}(\pi^+ \circ \gamma(x, y))(s)$ with the projection of

$X(s)$ on the normal bundle $N_{\gamma(x,y,s)}S$, i.e., we have the following decomposition

$$(2.13) \quad X(\gamma(x, y)) = X^{\text{ver}}(\pi^+ \circ \gamma(x, y)) + X^{\text{hor}}(\pi^+ \circ \gamma(x, y)),$$

where $X^{\text{hor}}(\pi^+ \circ \gamma(x, y)) \in \mathfrak{X}(\gamma(x, y)S)$. By construction, the vector fields $X^{\text{ver}}, Y^{\text{ver}}$ extend the tangent vectors u, v , so the torsion $T^\perp(u, v)$ is computed by $T^\perp(u, v) = (\nabla_{X^{\text{ver}}}^\perp Y^{\text{ver}} - \nabla_{Y^{\text{ver}}}^\perp X^{\text{ver}} - [X^{\text{ver}}, Y^{\text{ver}}])_{[u]}$. Since $X^{\text{ver}} = (\pi^+)_*X$ and $[X, Y] = 0$, we have $[X^{\text{ver}}, Y^{\text{ver}}] = 0$. The conclusion of the proof is then immediate from the following Lemma 2.8. \square

Lemma 2.8. *Assume that $X^{\text{ver}}, Y^{\text{ver}}$ are generated by γ defined in (2.11) and (2.13). Then we have*

$$(2.14) \quad \nabla_{X^{\text{ver}}}^\perp Y^{\text{ver}}_{[u]} = \nabla_{Y^{\text{ver}}}^\perp X^{\text{ver}}_{[u]} = 0.$$

Proof. As the statement is symmetric in X^{ver} and Y^{ver} , we only need to show that $\nabla_{X^{\text{ver}}}^\perp Y^{\text{ver}}_{[u]} = 0$. To prove Lemma 2.8, using (2.10), it suffices to show that for any $w \in \Gamma(N_\iota S)$ and any $s \in S$ we have

$$(2.15) \quad g(\gamma^*(\nabla^{LC;M})_{\frac{\partial}{\partial x}} Y^{\text{ver}}_{[\gamma]}|_{(x,y)=(0,0)}, w)_s = 0.$$

Since γ is a restriction of the exponential map $\text{Exp} : TM \rightarrow M$ at $\iota(S)$, we have

$$(2.16) \quad \gamma^*(\nabla^{LC;M})_{\frac{\partial}{\partial x}} Y_{[\gamma]}|_{(x,y)=(0,0)} = 0.$$

Using 2.16, to prove (2.15) it suffices to show that

$$(2.17) \quad g(\gamma^*(\nabla^{LC;M})_{\frac{\partial}{\partial x}} Y^{\text{hor}}_{[\gamma]}|_{(x,y)=(0,0)}, w)_s = 0.$$

Abusing the same notation γ , now we let γ be a map from $(-\varepsilon, \varepsilon) \times (-\varepsilon, \varepsilon) \times (-\varepsilon, \varepsilon) \times S \rightarrow M$ defined by (cf. (2.11))

$$(2.18) \quad \gamma(x, y, z, s) := \text{Exp}_{\iota(s)}(x \cdot u(s) + y \cdot v(s) + z \cdot w(s)),$$

and let Z be the vector field along the image of γ defined in analogy to X and Y . Then, as in (2.16), we have

$$(2.19) \quad \gamma^*(\nabla^{LC;M})_{\frac{\partial}{\partial x}} Z_{[\gamma]}|_{(x,y,z)=(0,0,0)} = 0.$$

and so equation (2.17) is equivalent to

$$(2.20) \quad \gamma^*(\nabla^{LC;M}) \frac{\partial}{\partial x} g(Y_{[\gamma]}^{\text{hor}}, Z_{[\gamma]})|_{(x,y,z)=(0,0,0)} = 0.$$

Noting that $g(Y^{\text{hor}}, Z^{\text{ver}}) = 0$, to prove (2.17) it suffices to show that

$$(2.21) \quad \gamma^*(\nabla^{LC;M}) \frac{\partial}{\partial x} g(Y_{[\gamma]}^{\text{hor}}, Z_{[\gamma]}^{\text{hor}})|_{(x,y,z)=(0,0,0)} = 0.$$

Since $Y \circ \gamma : (-\epsilon, \epsilon)^3 \times S \rightarrow TM$ is a differentiable map, the composition $Y^{\text{hor}} \circ \gamma : (-\epsilon, \epsilon)^3 \times S \rightarrow TM$ is a differentiable map. Since

$$Y^{\text{hor}} \circ \gamma(0, 0, 0, s) = 0,$$

we can write for $x \in [-\epsilon/2, \epsilon/2]$

$$(2.22) \quad Y^{\text{hor}} \circ \gamma(x, 0, 0, s) = x \cdot Y'(x, 0, 0, s)$$

where $Y'(x, 0, 0, s) \in T_{\gamma(x,0,0,s)}M$ and $|Y'(x, 0, 0, s)| \leq A(s)$ for some positive number $A(s) \in \mathbb{R}$. Since S is compact, we can choose $A(s)$ independent of s . The same argument applies to $Z \circ \gamma$. This yields (2.21) immediately and completes the proof of Lemma 2.8 \square

Next we shall define the desired symmetric tensor \mathfrak{B} . As (M, g) is a Riemannian manifold and S is oriented, we have a volume form map

$$\begin{aligned} \text{vol}_S : \text{Imm}_{i,f}(S, M) &\rightarrow \Omega^{\dim S}(S; \mathbb{R}) \\ \iota &\mapsto \text{vol}_{\iota^*g}, \end{aligned}$$

where $\text{vol}_{\iota^*g} \in \Omega^{\dim S}(S; \mathbb{R})$ denotes the volume form on S associated with the pullback metric ι^*g . As vol_S is a smooth function on $\text{Imm}_{i,f}(S, M)$ with values in a vector space, we can take its derivative $X \text{vol}_S$ with respect to a smooth vector field on $\text{Imm}_{i,f}(S, M)$ and this will again be a smooth $\Omega^{\dim S}(S; \mathbb{R})$ -valued function on $\text{Imm}_{i,f}(S, M)$. If $\tilde{\iota} = \iota \circ \phi$, then $\phi : (S, \iota^*g) \rightarrow (S, \tilde{\iota}^*g)$ is an isometry. This implies that the equation

$$(2.23) \quad g(X_{[\iota]}, W_{[\iota]})(\text{vol}_S)_{[\iota]} = (X \text{vol}_S)_{[\iota]}$$

for any vector field X on $B_{i,f}^+(S, M)$, is well-defined. Namely, the equivariance conditions $(\text{vol}_S)_{\tilde{\iota}} = \phi^*((\text{vol}_S)_{\iota})$ and $X_{\tilde{\iota}} = \phi^*X_{\iota}$ imply that a solution W is $\text{Diff}^+(S)$ -equivariant as well.

By the very definition of the mean curvature vector field for an immersed submanifold we have the following.

Lemma 2.9. *The equation 2.23 has a unique solution $W_{[\iota]} = -(\dim S)H_{\iota(S)}$, where $H_{\iota(S)}$ is the mean curvature of the immersed submanifold $\iota(S)$, defined by*

$$H_{\iota(S)} = \frac{1}{\dim S} \sum_{i=1}^{\dim S} (\nabla_{e_i}^{LC;M} e_i)^\perp,$$

where the e_i are orthonormal tangent vector fields on a neighborhood of a point s in S and \perp denotes the projection on the normal bundle. The solution $W_{[\iota]} = -(\dim S)H_{\iota(S)}$ defines a vector field W on $B_{i,f}^+(S, M)$.

Consider now the bilinear form

$$\mathfrak{B} : TB_{i,f}^+(S, M) \times TB_{i,f}^+(S, M) \rightarrow TB_{i,f}^+(S, M)$$

defined by

$$(2.24) \quad \mathfrak{B}(u, v)_{[\iota]} = g(u, v)W_{[\iota]} - g(u, W_{[\iota]})v - g(v, W_{[\iota]})u$$

for any $u, v \in T_{[\iota]}B_{i,f}^+(S, M)$, where W is the multiple of the mean curvature vector field defined in Lemma 2.9, and where we use the $C^\infty(S; \mathbb{R})$ -module structure on $T_{[\iota]}B_{i,f}^+(S, M) = N_\iota S$.

The following theorem generalizes to an arbitrary S results by Henrich for the cases $\dim S = 1$ and $\text{codim } S = 1$ [Henrich2009, Theorem 3.1, p. 25, Theorem 5.21, p. 50].

Theorem 2.10. *The covariant derivation $\nabla^\perp - \frac{1}{2}\mathfrak{B}$ is the Levi-Civita covariant derivation on $B_{i,f}^+(S, M)$.*

Proof. By uniqueness, we only need to show that $\nabla^\perp - \frac{1}{2}\mathfrak{B}$ is torsion-free and compatible with the Riemannian metric on $B_{i,f}^+(S, M)$. The torsion-freeness is immediate, as ∇^\perp is torsion-free, and \mathfrak{B} is a symmetric bilinear form. Next, we show that

$$X\langle Y, Z \rangle = \langle \nabla_X^\perp Y, Z \rangle + \langle Y, \nabla_X^\perp Z \rangle + -\frac{1}{2}(\langle \mathfrak{B}(X, Y), Z \rangle + \langle Y, \mathfrak{B}(X, Z) \rangle)$$

holds for any $X, Y, Z \in \mathfrak{X}(B_{i,f}^+(S, M))$. As the difference between the left and the right hand side of the above equation is a tensor, without loss of generality we can assume that X, Y, Z are generated by a three-parameter variation $\bar{\gamma} : \mathbb{R}^3 \rightarrow B_{i,f}^+(S, M)$ with $\bar{\gamma}(0, 0, 0) = [\iota]$, e.g., as in (2.18). The map

$\bar{\gamma}$ lifts to a smooth map $\gamma : (-\epsilon, \epsilon)^3 \rightarrow \text{Imm}_f(S, M)$ defined by a smooth map

$$\begin{aligned} \gamma : (-\epsilon, \epsilon) \times (-\epsilon, \epsilon) \times (-\epsilon, \epsilon) \times S &\rightarrow M, \\ (x, y, x, s) &\mapsto \gamma(x, y, z, s), \end{aligned}$$

with $\gamma(0, 0, 0, s) = \iota(s)$ and such that γ is purely normal at $(x, y, z) = (0, 0, 0)$. Then we can assume at every (x, y, z) we have

$$X = \left(\frac{d\gamma}{dx} \right)^{\text{ver}}, \quad Y = \left(\frac{d\gamma}{dy} \right)^{\text{ver}}, \quad Z = \left(\frac{d\gamma}{dz} \right)^{\text{ver}},$$

and find

$$\begin{aligned} (X\langle Y, Z \rangle)_{[l]} &= \frac{d}{dx} \int_S g(Y_{[\gamma]}, Z_{[\gamma]})(\text{vol}_S)_\gamma \Big|_{(x,y,z)=(0,0,0)} \\ &= \int_S \left(\frac{d}{dx} g(Y_{[\gamma]}, Z_{[\gamma]}) \right) (\text{vol}_S)_\gamma \Big|_{(x,y,z)=(0,0,0)} \\ &\quad + \int_S g(Y_{[\gamma]}, Z_{[\gamma]}) \left(\frac{d}{dx} (\text{vol}_S)_\gamma \right) \Big|_{(x,y,z)=(0,0,0)} \\ &= \int_S \left(g(\gamma^*(\nabla^{LC;M})_{\frac{\partial}{\partial x}} Y_{[\gamma]}, Z_{[\gamma]}) \right. \\ &\quad \left. + g(Y_{[\gamma]}, \gamma^*(\nabla^{LC;M})_{\frac{\partial}{\partial x}} Z_{[\gamma]}) \right) (\text{vol}_S)_\gamma \Big|_{(x,y,z)=(0,0,0)} \\ &\quad + \int_S g(Y_{[\gamma]}, Z_{[\gamma]}) \left(\frac{d}{dx} (\text{vol}_S)_\gamma \right) \Big|_{(x,y,z)=(0,0,0)} \\ &= \int_S \left(g((\nabla_X^\perp Y)_{[l]}, Z_{[l]}) + g(Y_{[l]}, (\nabla_X^\perp Z)_{[l]}) \right) (\text{vol}_S)_{[l]} \\ &\quad + \int_S g(Y_{[l]}, Z_{[l]})(X \text{vol}_S)_{[l]} \\ &= \langle \nabla_X^\perp Y, Z \rangle_{[l]} + \langle Y, \nabla_X^\perp Z \rangle_{[l]} \\ &\quad + \int_S g(X_{[l]}, W_{[l]}) g(Y_{[l]}, Z_{[l]})(\text{vol}_S)_{[l]}. \end{aligned}$$

In the above equation we used that, as $Z_{[l]} = Z_{[l]}^{\text{ver}}$, we have

$$\begin{aligned} &g(\gamma^*(\nabla^{LC;M})_{\frac{\partial}{\partial x}} Y_{[\gamma]}, Z_{[\gamma]}) \Big|_{(x,y,z)=(0,0,0)} \\ &= g((\gamma^*(\nabla^{LC;M})_{\frac{\partial}{\partial x}} Y_{[\gamma]})^\perp, Z_{[\gamma]}) \Big|_{(x,y,z)=(0,0,0)} = g((\nabla_X^\perp Y)_{[l]}, Z_{[l]}). \end{aligned}$$

Therefore, we are reduced to showing that

$$\int_S g(X_{[\iota]}, W_{[\iota]})g(Y_{[\iota]}, Z_{[\iota]})(\text{vol}_S)_{[\iota]} = -\frac{\langle \mathfrak{B}(X, Y), Z \rangle + \langle Y, \mathfrak{B}(X, Z) \rangle}{2},$$

which is straightforward from the definition of \mathfrak{B} . □

Remark 2.11. In [MMM2013, (8)], see also [Michor2016, §4.2], Micheli, Michor, and Mumford give more generally an existence condition for the Levi-Civita covariant derivative on a smooth manifold M modeled on convenient locally convex vector spaces and endowed with a weak Riemannian metric g , i.e. a symmetric positive definite bilinear form g such that $g_x^b : T_x M \rightarrow T_x^* M$ is only injective for each $x \in M$, in terms of symmetric gradients with respect to g .

3. The formally Kähler structure of higher dimensional knot spaces

In this section we give a proof of our Main Theorem 1.3. First we recall Lee-Leung’s construction of the almost complex structure J on $B_{i,f}^+(S, M)$ associated with a VCP on M . Then we derive Theorem 1.3 from Corollary 3.4 and Proposition 3.5.

Denote by $Gr^+(r, M)$ the Grassmanian bundle over (M, g) whose fiber over $p \in M$ consists of the Grassmanian manifold of oriented r -dimensional subspaces in $T_p M$. For $v \in Gr_p^+(r, M)$ let us denote by \vec{v} the oriented unit r -vector associated to v and to the Riemannian metric g of M , and by v^\perp the oriented orthogonal complement to v in $T_p M$. Lee-Leung made the following simple but crucial observation [LL2007, p. 146]

Lemma 3.1. *Let $\chi \in \Omega^{r+1}(M, TM)$ be a VCP. Then for any $v \in Gr_p^+(r, M)$ and any $\xi \in v^\perp \subset T_p M$ we have*

$$i_{\vec{v}} \chi_p(\xi) \in v^\perp.$$

Furthermore, the restriction of $i_{\vec{v}} \chi_p$ to v^\perp is a 1-fold VCP on v^\perp , denoted by $J(\chi, v)$, which satisfies the following relation for any $\xi, \zeta \in v^\perp$

$$(3.1) \quad i_{\vec{v}}(\varphi_\chi)_p(\xi, \zeta) = g_p(J(\chi, v)\xi, \zeta),$$

where φ_χ is the VPC-form of χ (equation (1.1)).

We observe that Lemma 3.1 is a consequence of Gray’s theorem [Gray1969, Theorem 2.6].

Remark 3.2. As 1-VCP on Euclidean vector spaces are equivalent to linear Kähler structures, one is naturally led to considering the Hermitian vector bundle $E(\chi)$ over $Gr^+(r, M)$ whose fiber over v is v^\perp with the Hermitian structure $(g, J(\chi, v))$. As Chern classes are deformation invariants of the complex structure on a real vector bundle, the Chern classes of $E(\chi)$ are deformation invariants of the VCP structure χ on M . A detailed investigation of these and other deformation invariants of a VCP structure with emphasis on G_2 - and torsion-free Spin(7)-manifolds, as well as a comparison with known deformation invariants of G_2 -structures [CGN2018] will appear elsewhere.

Assume the dimension of the closed oriented manifold S is $\dim_{\mathbb{R}} S = r$. At each point (s, ι) in $S \times \text{Imm}_f(S, M)$, the image ι_*T_sS of the tangent space T_sS in $T_{\iota(s)}M$ defines an element in $Gr^+(r, M)$, so we have defined a smooth map

$$v: S \times \text{Imm}_f(S, M) \rightarrow Gr^+(r, M).$$

By construction, $v^\perp(s, \iota) = N_{\iota(s)}S$, so by Lemma 3.1 we have a pointwise 1-VCP on the fibres of the normal bundle to S at ι , compatible with the inner product induced from M . From this it follows that we have the linear operator J on the tangent bundle $TB_{i,f}^+(S, M)$ defined by setting, at each point $[\iota: S \rightarrow M]$,

$$(3.2) \quad (J_{[\iota]}X)_s := i \frac{\iota_*}{\iota_*T_sS} \chi_{\iota(s)}(X_s).$$

Lee and Leung observed that J is an almost complex structure on $TB(S, M)$ [LL2007, p. 146], compatible with the L_2 -metric, thus endowing $B_{i,f}^+(S, M)$ with the structure of an almost Hermitian manifold. As the fundamental 2-form of this Hermitian structure is the transgression defined by (2.2) of the $(r + 2)$ -VCP-form φ_χ defined in (1.1), [LL2007, Lemma 7], one sees that if φ_χ is closed, then $B_{i,f}^+(S, M)$ is an almost Kähler manifold.

In the remaining part of this section we assume that χ is a parallel VCP on (M, g) . In particular, this implies that φ_χ is closed.

Proposition 3.3. *The almost complex structure J is parallel with respect to the affine connection ∇^\perp of equation (2.10), i.e. $\nabla^\perp J = 0$. Equivalently, ∇^\perp is an almost complex connection with respect to the almost complex structure J .*

Proof. We need to prove that $\nabla_X^\perp J = 0$ for any vector field X on $B_{i,f}^+(S, M)$. As $(\nabla_X^\perp J)Y = \nabla_X^\perp(JY) - J(\nabla_X^\perp Y)$, this is equivalent to proving

$$(3.3) \quad \langle \nabla_X^\perp(JY) - J(\nabla_X^\perp Y), Z \rangle_{[\iota]} = 0$$

for any three vector fields X, Y, Z on $B_{i,f}^+(S, M)$, and any point $[\iota] \in B_{i,f}^+(S, M)$. Since the left hand side of (3.3) is a tensor, without loss of generality, as in the proof of Theorem 2.10, we assume that X, Y, Z are the vertical vector fields generated by the three-parameter variation

$$\begin{aligned} \gamma : (-\epsilon, \epsilon) \times (-\epsilon, \epsilon) \times (-\epsilon, \epsilon) \times S &\rightarrow M \\ (x, y, z, s) &\mapsto \gamma(x, y, z, s), \\ \gamma(0, 0, 0, s) &= \iota(s) \end{aligned}$$

defined by (2.18) and therefore we can apply Lemma 2.8, giving $\nabla_X^\perp Y = 0$. From the defining equation (2.18), the restrictions of the vertical vector fields X, Y and Z at $(x, y, z) = (0, 0, 0)$ are the sections u, v and w of $N_\iota S$, respectively. We are then reduced to proving that

$$\langle \nabla_X^\perp(JY), Z \rangle_{[\iota]} = 0,$$

i.e., due to fact that by (2.10) the value $\nabla_X^\perp(JY)_{\iota(s)}$ depends only on $u(s)$ and due to the arbitrariness of the restriction w of Z at $[\iota]$, to show that

$$(3.4) \quad g(\nabla_u^\perp(JY), w)_{\iota(s)} = 0$$

for Y the vertical vector field defined by (2.18), for any $u, w \in \Gamma(N_\iota S)$ and for all $s \in S$, which we prove next.

From the definition of ∇^\perp , equation (2.10), and the definition of J , equation (3.2), we get

$$(3.5) \quad g(\nabla_u^\perp(JY), w)_{\iota(s)} = g((\gamma^*(\nabla^{LC;M})_{\frac{\partial}{\partial x}} \chi(\overrightarrow{T_{\gamma(x,s)}\gamma(x)(S)}, Y))^\perp, w)_{\iota(s)}.$$

As χ is parallel with respect to the Levi-Civita connection on M , and since $w \in \Gamma(N_\iota S)$, we get

$$\begin{aligned} g(\nabla_u^\perp(JY), w)_{\iota(s)} &= g(\gamma^*(\nabla^{LC;M})_{\frac{\partial}{\partial x}} \chi(\overrightarrow{T_{[\gamma]}\dot{S}}, Y), w)_{\iota(s)} \\ &= g(\chi(\gamma^*(\nabla^{LC;M})_{\frac{\partial}{\partial x}} \overrightarrow{T_{[\gamma]}\dot{S}}, v), w)_{\iota(s)} + g(J\nabla_X^\perp Y, w)_{\iota(s)} \\ &= \varphi_\chi(\gamma^*(\nabla^{LC;M})_{\frac{\partial}{\partial x}} \overrightarrow{T_{[\gamma]}\dot{S}}, v, w)_{\iota(s)}, \end{aligned}$$

where we used $\nabla_X^\perp Y = 0$ from Lemma 2.8.

Let $E_1(x, s), \dots, E_r(x, s)$ be the basis of $T_{\gamma(x,s)}\gamma(x)S$ obtained by the exponential flow in the direction X from an orthonormal basis $e_1(s), \dots, e_r(s)$ of $T_{\iota(s)}\iota(S) \subset T_{\iota(s)}M$, so that

$$\overrightarrow{T_{\gamma(x,s)}\gamma(x)S} = \text{vol}(E_1(x, s) \wedge \dots \wedge E_r(x, s))^{-1} E_1(x, s) \wedge \dots \wedge E_r(x, s).$$

Then we have

(3.6)

$$\begin{aligned} & \varphi_\chi(\gamma^*(\nabla^{LC;M}) \frac{\partial}{\partial x} \overrightarrow{T_{[\gamma]S}}|_{x=0}, v, w) \\ &= \gamma^*(\nabla^{LC;M}) \frac{\partial}{\partial x} ((\text{vol}(E_1(x, s) \wedge \dots \wedge E_r(x, s))^{-1})|_{x=0}) \varphi_\chi(e_1, \dots, e_r, v, w) \\ &+ \sum_{i=1}^r \varphi(e_1, \dots, \gamma^*(\nabla^{LC;M}) \frac{\partial}{\partial x} E_i|_{x=0}, \dots, e_r, v, w). \end{aligned}$$

From the defining equation (2.23) for the gradient vector field W we have

$$\begin{aligned} & \gamma^*(\nabla^{LC;M}) \frac{\partial}{\partial x} ((\text{vol}(E_1(x, s) \wedge \dots \wedge E_r(x, s))^{-1})|_{x=0}) \\ &= -g(u, W_{[\iota]}), \end{aligned}$$

so equation (3.6) becomes

$$\begin{aligned} (3.7) \quad & \varphi_\chi(\gamma^*(\nabla^{LC;M}) \frac{\partial}{\partial x} \overrightarrow{T_{[\gamma]S}}|_{x=0}, v, w) \\ &= -g(u, W_{[\iota]}) \varphi_\chi(e_1, \dots, e_r, v, w) \\ &+ \sum_{i=1}^r \varphi_\chi(e_1, \dots, \gamma^*(\nabla^{LC;M}) \frac{\partial}{\partial x} E_i|_{x=0}, \dots, e_r, v, w) \end{aligned}$$

Denote by $(\gamma^*(\nabla^{LC;M}) \frac{\partial}{\partial x} E_i)|_{x=0}^T$ the projection of $(\gamma^*(\nabla^{LC;M}) \frac{\partial}{\partial x} E_i)|_{x=0}$ to $T\iota(S)$, and by $(\gamma^*(\nabla^{LC;M}) \frac{\partial}{\partial x} E_i)|_{x=0}^\perp$ the projection on the normal bundle. As the Levi-Civita connection $\nabla^{LC;M}$ is torsionless and compatible with the metric g on M , we have

$$(\gamma^*(\nabla^{LC;M}) \frac{\partial}{\partial x} E_i)|_{x=0}^T = (\nabla_{e_i}^{LC;M} u)^T = \sum_{j=1}^r g(\nabla_{e_i}^{LC;M} u, e_j) e_j.$$

Therefore

$$\begin{aligned} & \sum_{i=1}^r \varphi_\chi(e_1, \dots, \gamma^*(\nabla^{LC;M}) \frac{\partial}{\partial x} E_i \Big|_{x=0}^T, \dots, e_r, v, w) \\ &= \left(\sum_{i=1}^r g(\nabla_{e_i}^{LC;M} u, e_i) \right) \varphi_\chi(e_1, \dots, e_r, v, w). \end{aligned}$$

As u is a normal vector field on $\iota(S)$ while e_i is a tangent vector field, we have that $g(u, e_i)$ is identically zero on S and so by applying $\nabla_{e_i}^{LC;M}$ we find

$$g(u, (\nabla_{e_i}^{LC;M} e_i)^\perp) = -g(\nabla_{e_i}^{LC;M} u, e_i).$$

By Lemma 2.9 we therefore get

$$g(u, W_{[l]}) = \sum_{i=1}^r g(\nabla_{e_i}^{LC;M} u, e_i).$$

Equation (3.7) then reduces to

$$\begin{aligned} (3.8) \quad & \varphi_\chi(\gamma^*(\nabla^{LC;M}) \overrightarrow{\frac{\partial}{\partial x} T_{[\gamma]} \dot{S}} \Big|_{x=0}, v, w) \\ &= \sum_{i=1}^r \varphi_\chi(e_1, \dots, (\nabla_{e_i}^{LC;M} u)^\perp, \dots, e_r, v, w) \end{aligned}$$

and so we have obtained the identity

$$(3.9) \quad g(\nabla_u^\perp(JY), w)_{\iota(s)} = \sum_{i=1}^r \varphi_\chi(e_1, \dots, (\nabla_{e_i}^{LC;M} u)^\perp, \dots, e_r, v, w)_s$$

for any sections u, v, w of $N_\iota S$ and for any extension Y of v to a vertical vector field along a three-parameter deformation γ of ι by equation (2.18). As for fixed v and w the left hand side of equation (3.9) only depends on the value of u at s , it is not restrictive to assume $(\nabla_{e_i}^{LC;M} u)^\perp_s = 0$ for every $i = 1, \dots, r$. Therefore $g(\nabla_u^\perp(JY), w)_{\iota(s)} = 0$, as we wanted to prove. \square

Let us recall the expression of the Nijenhuis tensor N_J of an almost complex structure J on a smooth manifold \mathfrak{M} , see e.g., [KN1969, p. 123].

$$(3.10) \quad N_J(X, Y) := 2([JX, JY] - [X, Y] - J[X, JY] - J[JX, Y])$$

for $X, Y \in \mathfrak{X}(\mathfrak{M})$. Moreover, if ∇ is an almost complex affine connection with respect to the almost complex structure J , by Proposition 3.6 in [KN1969,

p. 145], we have

$$(3.11) \quad N_J(X, Y) = -2(T(JX, JY) - J(T(JX, Y)) \\ - J(T(X, JY)) - T(X, Y)),$$

where T is the torsion of ∇ . It is noteworthy that the proof of Proposition 3.6 *ibid.* works not only for the case of finite dimensional manifolds \mathfrak{M} , but also for infinite dimensional manifolds for which affine connections and Lie brackets of vector fields can be defined. Namely, the argument *ibid.* uses the expression for T defined in (2.8), and then applies it to the RHS of (3.11). Summing up, the RHS of (3.11) is written as a sum of eight summands involving ∇ and four summands involving the Lie brackets. Since ∇ commute with J by definition of almost complex affine connection, the sum of the eight summands involving ∇ vanishes. Then they observe that the sum of the four summands involving the Lie brackets is equal to the RHS of (3.10). This proves (3.11).

In particular, this applies to the infinite dimensional manifold $B_{i,f}^+(S, M)$ As ∇^\perp is torsion-free by Proposition 2.7, and it is almost complex with respect to the almost complex structure J by Proposition 3.3, we get the following.

Corollary 3.4. *The almost complex structure J on $B_{i,f}^+(S, M)$ satisfies $N_J = 0$ and so it is a formally integrable almost complex structure.*

Proposition 3.5. *The almost complex structure J is parallel with respect to the Levi-Civita connection ∇^{LC} . Equivalently, ∇^{LC} is an almost complex connection with respect to the almost complex structure J .*

Proof. We already know that $B_{i,f}^+(S, M)$ is a smooth manifold endowed with the formally integrable almost complex structure J , defined by (3.2), and with the L_2 -metric, which is compatible with J and so defines a formally Kähler structure. As the fundamental 2-form ω of the formally Kähler metric is closed, by [KN1969, Proposition 4.2, p. 148]¹ we then have

$$4\langle (\nabla_X^{LC} J)Y, Z \rangle = \langle N_J(Y, Z), JX \rangle = 0$$

for any three vector fields X, Y, Z on $B_{i,f}^+(S, M)$, hence $\nabla^{LC} J = 0$. \square

¹Kobayashi-Nomizdu gave a proof of Proposition 4.2 *ibid.* that is also valid for infinite dimensional manifolds locally modeled on convenient vector spaces, since the standard formula for $d\omega$ *ibid.* is also valid in the convenient setting [KM1997, (3), p. 342].

Proof of Theorem 1.3. Theorem 1.3 follows from Proposition 3.5 and Corollary 3.4. \square
